The `VFtoVP` processor

(Version 1.4, January 2014)

July 9, 2024 at 19:32

1. Introduction. The VFtoVP utility program converts a virtual font ("VF") file and its associated TEX font metric ("TFM") file into an equivalent virtual-property-list ("VPL") file. It also makes a thorough check of the given files, using algorithms that are essentially the same as those used by DVI device drivers and by TEX. Thus if TEX or a DVI driver complains that a TFM or VF file is "bad," this program will pinpoint the source or sources of badness. A VPL file output by this program can be edited with a normal text editor, and the result can be converted back to VF and TFM format using the companion program VPtoVF.

VFtoVP is an extended version of the program TFtoPL, which is part of the standard TEXware library. The idea of a virtual font was inspired by the work of David R. Fuchs who designed a similar set of conventions in 1984 while developing a device driver for ArborText, Inc. He wrote a somewhat similar program called AMFtoXPL.

The *banner* string defined here should be changed whenever VFtoVP gets modified.

define *banner* ≡ ´This␣is␣VFtoVP,␣Version␣1.4´   { printed when the program starts }

2. This program is written entirely in standard Pascal, except that it occasionally has lower case letters in strings that are output. Such letters can be converted to upper case if necessary. The input is read from *vf_file* and *tfm_file*; the output is written on *vpl_file*. Error messages and other remarks are written on the *output* file, which the user may choose to assign to the terminal if the system permits it.

The term *print* is used instead of *write* when this program writes on the *output* file, so that all such output can be easily deflected.

define *print*(#) ≡ *write*(#)
define *print_ln*(#) ≡ *write_ln*(#)

program *VFtoVP*(*vf_file*, *tfm_file*, *vpl_file*, *output*);
  label ⟨ Labels in the outer block 3 ⟩
  const ⟨ Constants in the outer block 4 ⟩
  type ⟨ Types in the outer block 5 ⟩
  var ⟨ Globals in the outer block 7 ⟩
  procedure *initialize*;   { this procedure gets things started properly }
    var *k*: *integer*;   { all-purpose index for initialization }
    begin *print_ln*(*banner*);
    ⟨ Set initial values 11 ⟩
    end;

3. If the program has to stop prematurely, it goes to the '*final_end*'.

define *final_end* = 9999   { label for the end of it all }

⟨ Labels in the outer block 3 ⟩ ≡
  final_end;
This code is used in section 2.

4. The following parameters can be changed at compile time to extend or reduce VFtoVP's capacity.

⟨ Constants in the outer block 4 ⟩ ≡
  tfm_size = 30000;   { maximum length of *tfm* data, in bytes }
  vf_size = 10000;   { maximum length of *vf* data, in bytes }
  max_fonts = 300;   { maximum number of local fonts in the *vf* file }
  lig_size = 5000;   { maximum length of *lig_kern* program, in words }
  hash_size = 5003;
    { preferably a prime number, a bit larger than the number of character pairs in lig/kern steps }
  name_length = 50;   { a file name shouldn't be longer than this }
  max_stack = 50;   { maximum depth of DVI stack in character packets }
This code is used in section 2.

5.   Here are some macros for common programming idioms.

> **define** $incr(\#) \equiv \# \leftarrow \# + 1$ { increase a variable by unity }
> **define** $decr(\#) \equiv \# \leftarrow \# - 1$ { decrease a variable by unity }
> **define** $do\_nothing \equiv$ { empty statement }
> **define** $exit = 10$ { go here to leave a procedure }
> **define** $not\_found = 45$ { go here when you've found nothing }
> **define** $return \equiv$ **goto** $exit$ { terminate a procedure call }
> **format** $return \equiv nil$

⟨ Types in the outer block 5 ⟩ ≡
   $byte = 0 \mathinner{.\,.} 255$;   { unsigned eight-bit quantity }

See also section 22.

This code is used in section 2.

6. Virtual fonts.   The idea behind VF files is that a general interface mechanism is needed to switch between the myriad font layouts provided by different suppliers of typesetting equipment. Without such a mechanism, people must go to great lengths writing inscrutable macros whenever they want to use typesetting conventions based on one font layout in connection with actual fonts that have another layout. This puts an extra burden on the typesetting system, interfering with the other things it needs to do (like kerning, hyphenation, and ligature formation).

These difficulties go away when we have a "virtual font," i.e., a font that exists in a logical sense but not a physical sense. A typesetting system like TEX can do its job without knowing where the actual characters come from; a device driver can then do its job by letting a VF file tell what actual characters correspond to the characters TEX imagined were present. The actual characters can be shifted and/or magnified and/or combined with other characters from many different fonts. A virtual font can even make use of characters from virtual fonts, including itself.

Virtual fonts also allow convenient character substitutions for proofreading purposes, when fonts designed for one output device are unavailable on another.

7.   A VF file is organized as a stream of 8-bit bytes, using conventions borrowed from DVI and PK files. Thus, a device driver that knows about DVI and PK format will already contain most of the mechanisms necessary to process VF files. We shall assume that DVI format is understood; the conventions in the DVI documentation (see, for example, *TEX: The Program*, part 31) are adopted here to define VF format.

A preamble appears at the beginning, followed by a sequence of character definitions, followed by a postamble. More precisely, the first byte of every VF file must be the first byte of the following "preamble command":

> *pre* 247 $i[1]$ $k[1]$ $x[k]$ $cs[4]$ $ds[4]$. Here i is the identification byte of VF, currently 202. The string x is merely a comment, usually indicating the source of the VF file. Parameters cs and ds are respectively the check sum and the design size of the virtual font; they should match the first two words in the header of the TFM file, as described below.

After the *pre* command, the preamble continues with font definitions; every font needed to specify "actual" characters in later *set_char* commands is defined here. The font definitions are exactly the same in VF files as they are in DVI files, except that the scaled size s is relative and the design size d is absolute:

> *fnt_def1* 243 $k[1]$ $c[4]$ $s[4]$ $d[4]$ $a[1]$ $l[1]$ $n[a+l]$. Define font k, where $0 \le k < 256$.
>
> *fnt_def2* 244 $k[2]$ $c[4]$ $s[4]$ $d[4]$ $a[1]$ $l[1]$ $n[a+l]$. Define font k, where $0 \le k < 65536$.
>
> *fnt_def3* 245 $k[3]$ $c[4]$ $s[4]$ $d[4]$ $a[1]$ $l[1]$ $n[a+l]$. Define font k, where $0 \le k < 2^{24}$.
>
> *fnt_def4* 246 $k[4]$ $c[4]$ $s[4]$ $d[4]$ $a[1]$ $l[1]$ $n[a+l]$. Define font k, where $-2^{31} \le k < 2^{31}$.

These font numbers k are "local"; they have no relation to font numbers defined in the DVI file that uses this virtual font. The dimension s, which represents the scaled size of the local font being defined, is a *fix_word* relative to the design size of the virtual font. Thus if the local font is to be used at the same size as the design size of the virtual font itself, s will be the integer value 2^{20}. The value of s must be positive and less than 2^{24} (thus less than 16 when considered as a *fix_word*). The dimension d is a *fix_word* in units of printer's points; hence it is identical to the design size found in the corresponding TFM file.

> **define** $id\_byte = 202$

⟨ Globals in the outer block 7 ⟩ ≡
vf_file: **packed file of** *byte*;

See also sections 10, 12, 20, 23, 26, 29, 30, 37, 42, 49, 51, 54, 67, 69, 85, 87, 111, and 123.

This code is used in section 2.

8.   The preamble is followed by zero or more character packets, where each character packet begins with a byte that is < 243. Character packets have two formats, one long and one short:

   long_char 242 *pl*[4] *cc*[4] *tfm*[4] *dvi*[*pl*]. This long form specifies a virtual character in the general case.

   short_char0 .. *short_char241* *pl*[1] *cc*[1] *tfm*[3] *dvi*[*pl*]. This short form specifies a virtual character in the common case when $0 \le pl < 242$ and $0 \le cc < 256$ and $0 \le tfm < 2^{24}$.

Here *pl* denotes the packet length following the *tfm* value; *cc* is the character code; and *tfm* is the character width copied from the TFM file for this virtual font. There should be at most one character packet having any given *cc* code.

   The *dvi* bytes are a sequence of complete DVI commands, properly nested with respect to *push* and *pop*. All DVI operations are permitted except *bop*, *eop*, and commands with opcodes ≥ 243. Font selection commands (*fnt_num0* through *fnt4*) must refer to fonts defined in the preamble.

   Dimensions that appear in the DVI instructions are analogous to *fix_word* quantities; i.e., they are integer multiples of 2^{-20} times the design size of the virtual font. For example, if the virtual font has design size 10 pt, the DVI command to move down 5 pt would be a *down* instruction with parameter 2^{19}. The virtual font itself might be used at a different size, say 12 pt; then that *down* instruction would move down 6 pt instead. Each dimension must be less than 2^{24} in absolute value.

   Device drivers processing VF files treat the sequences of *dvi* bytes as subroutines or macros, implicitly enclosing them with *push* and *pop*. Each subroutine begins with $w = x = y = z = 0$, and with current font *f* the number of the first-defined in the preamble (undefined if there's no such font). After the *dvi* commands have been performed, the *h* and *v* position registers of DVI format and the current font *f* are restored to their former values; then, if the subroutine has been invoked by a *set_char* or *set* command, *h* is increased by the TFM width (properly scaled)—just as if a simple character had been typeset.

   define *long_char* = 242   { VF command for general character packet }
   define *set_char_0* = 0   { DVI command to typeset character 0 and move right }
   define *set1* = 128   { typeset a character and move right }
   define *set_rule* = 132   { typeset a rule and move right }
   define *put1* = 133   { typeset a character }
   define *put_rule* = 137   { typeset a rule }
   define *nop* = 138   { no operation }
   define *push* = 141   { save the current positions }
   define *pop* = 142   { restore previous positions }
   define *right1* = 143   { move right }
   define *w0* = 147   { move right by *w* }
   define *w1* = 148   { move right and set *w* }
   define *x0* = 152   { move right by *x* }
   define *x1* = 153   { move right and set *x* }
   define *down1* = 157   { move down }
   define *y0* = 161   { move down by *y* }
   define *y1* = 162   { move down and set *y* }
   define *z0* = 166   { move down by *z* }
   define *z1* = 167   { move down and set *z* }
   define *fnt_num_0* = 171   { set current font to 0 }
   define *fnt1* = 235   { set current font }
   define *xxx1* = 239   { extension to DVI primitives }
   define *xxx4* = 242   { potentially long extension to DVI primitives }
   define *fnt_def1* = 243   { define the meaning of a font number }
   define *pre* = 247   { preamble }
   define *post* = 248   { postamble beginning }
   define *improper_DVI_for_VF* $\equiv$ 139, 140, 243, 244, 245, 246, 247, 248, 249, 250, 251, 252, 253, 254, 255

9.   The character packets are followed by a trivial postamble, consisting of one or more bytes all equal to *post* (248). The total number of bytes in the file should be a multiple of 4.

10.   Font metric data.   The idea behind TFM files is that typesetting routines like TEX need a compact way to store the relevant information about several dozen fonts, and computer centers need a compact way to store the relevant information about several hundred fonts. TFM files are compact, and most of the information they contain is highly relevant, so they provide a solution to the problem.

The information in a TFM file appears in a sequence of 8-bit bytes. Since the number of bytes is always a multiple of 4, we could also regard the file as a sequence of 32-bit words; but TEX uses the byte interpretation, and so does VFtoVP. Note that the bytes are considered to be unsigned numbers.

⟨ Globals in the outer block 7 ⟩ +≡
tfm_file: **packed file of** *byte*;

11.   On some systems you may have to do something special to read a packed file of bytes. For example, the following code didn't work when it was first tried at Stanford, because packed files have to be opened with a special switch setting on the Pascal that was used.

⟨ Set initial values 11 ⟩ ≡
  reset(*tfm_file*); *reset*(*vf_file*);

See also sections 21, 43, 50, 55, 68, and 86.

This code is used in section 2.

12.   The first 24 bytes (6 words) of a TFM file contain twelve 16-bit integers that give the lengths of the various subsequent portions of the file. These twelve integers are, in order:

$$lf = \text{length of the entire file, in words;}$$
$$lh = \text{length of the header data, in words;}$$
$$bc = \text{smallest character code in the font;}$$
$$ec = \text{largest character code in the font;}$$
$$nw = \text{number of words in the width table;}$$
$$nh = \text{number of words in the height table;}$$
$$nd = \text{number of words in the depth table;}$$
$$ni = \text{number of words in the italic correction table;}$$
$$nl = \text{number of words in the lig/kern table;}$$
$$nk = \text{number of words in the kern table;}$$
$$ne = \text{number of words in the extensible character table;}$$
$$np = \text{number of font parameter words.}$$

They are all nonnegative and less than 2^{15}. We must have $bc - 1 \le ec \le 255$, $ne \le 256$, and

$$lf = 6 + lh + (ec - bc + 1) + nw + nh + nd + ni + nl + nk + ne + np.$$

Note that a font may contain as many as 256 characters (if $bc = 0$ and $ec = 255$), and as few as 0 characters (if $bc = ec + 1$).

Incidentally, when two or more 8-bit bytes are combined to form an integer of 16 or more bits, the most significant bytes appear first in the file. This is called BigEndian order.

⟨ Globals in the outer block 7 ⟩ +≡
lf, *lh*, *bc*, *ec*, *nw*, *nh*, *nd*, *ni*, *nl*, *nk*, *ne*, *np*: 0 .. ´77777´;   { subfile sizes }

13. The rest of the `TFM` file may be regarded as a sequence of ten data arrays having the informal specification

$$header : \textbf{array} \; [0 .. \mathit{lh} - 1] \; \textbf{of} \; \mathit{stuff}$$
$$\mathit{char\_info} : \textbf{array} \; [\mathit{bc} .. \mathit{ec}] \; \textbf{of} \; \mathit{char\_info\_word}$$
$$width : \textbf{array} \; [0 .. \mathit{nw} - 1] \; \textbf{of} \; \mathit{fix\_word}$$
$$height : \textbf{array} \; [0 .. \mathit{nh} - 1] \; \textbf{of} \; \mathit{fix\_word}$$
$$depth : \textbf{array} \; [0 .. \mathit{nd} - 1] \; \textbf{of} \; \mathit{fix\_word}$$
$$italic : \textbf{array} \; [0 .. \mathit{ni} - 1] \; \textbf{of} \; \mathit{fix\_word}$$
$$\mathit{lig\_kern} : \textbf{array} \; [0 .. \mathit{nl} - 1] \; \textbf{of} \; \mathit{lig\_kern\_command}$$
$$kern : \textbf{array} \; [0 .. \mathit{nk} - 1] \; \textbf{of} \; \mathit{fix\_word}$$
$$exten : \textbf{array} \; [0 .. \mathit{ne} - 1] \; \textbf{of} \; \mathit{extensible\_recipe}$$
$$param : \textbf{array} \; [1 .. \mathit{np}] \; \textbf{of} \; \mathit{fix\_word}$$

The most important data type used here is a $\mathit{fix\_word}$, which is a 32-bit representation of a binary fraction. A $\mathit{fix\_word}$ is a signed quantity, with the two's complement of the entire word used to represent negation. Of the 32 bits in a $\mathit{fix\_word}$, exactly 12 are to the left of the binary point; thus, the largest $\mathit{fix\_word}$ value is $2048 - 2^{-20}$, and the smallest is -2048. We will see below, however, that all but one of the $\mathit{fix\_word}$ values will lie between -16 and $+16$.

14. The first data array is a block of header information, which contains general facts about the font. The header must contain at least two words, and for TFM files to be used with Xerox printing software it must contain at least 18 words, allocated as described below. When different kinds of devices need to be interfaced, it may be necessary to add further words to the header block.

$header[0]$ is a 32-bit check sum that TeX will copy into the DVI output file whenever it uses the font. Later on when the DVI file is printed, possibly on another computer, the actual font that gets used is supposed to have a check sum that agrees with the one in the TFM file used by TeX. In this way, users will be warned about potential incompatibilities. (However, if the check sum is zero in either the font file or the TFM file, no check is made.) The actual relation between this check sum and the rest of the TFM file is not important; the check sum is simply an identification number with the property that incompatible fonts almost always have distinct check sums.

$header[1]$ is a *fix_word* containing the design size of the font, in units of TeX points (7227 TeX points = 254 cm). This number must be at least 1.0; it is fairly arbitrary, but usually the design size is 10.0 for a "10 point" font, i.e., a font that was designed to look best at a 10-point size, whatever that really means. When a TeX user asks for a font 'at δ pt', the effect is to override the design size and replace it by δ, and to multiply the x and y coordinates of the points in the font image by a factor of δ divided by the design size. *All other dimensions in the TFM file are fix_word numbers in design-size units.* Thus, for example, the value of $param[6]$, one em or \quad, is often the *fix_word* value $2^{20} = 1.0$, since many fonts have a design size equal to one em. The other dimensions must be less than 16 design-size units in absolute value; thus, $header[1]$ and $param[1]$ are the only *fix_word* entries in the whole TFM file whose first byte might be something besides 0 or 255.

$header[2 .. 11]$, if present, contains 40 bytes that identify the character coding scheme. The first byte, which must be between 0 and 39, is the number of subsequent ASCII bytes actually relevant in this string, which is intended to specify what character-code-to-symbol convention is present in the font. Examples are ASCII for standard ASCII, TeX text for fonts like cmr10 and cmti9, TeX math extension for cmex10, XEROX text for Xerox fonts, GRAPHIC for special-purpose non-alphabetic fonts, UNSPECIFIED for the default case when there is no information. Parentheses should not appear in this name. (Such a string is said to be in BCPL format.)

$header[12 .. 16]$, if present, contains 20 bytes that name the font family (e.g., CMR or HELVETICA), in BCPL format. This field is also known as the "font identifier."

$header[17]$, if present, contains a first byte called the *seven_bit_safe_flag*, then two bytes that are ignored, and a fourth byte called the *face*. If the value of the fourth byte is less than 18, it has the following interpretation as a "weight, slope, and expansion": Add 0 or 2 or 4 (for medium or bold or light) to 0 or 1 (for roman or italic) to 0 or 6 or 12 (for regular or condensed or extended). For example, 13 is 0+1+12, so it represents medium italic extended. A three-letter code (e.g., MIE) can be used for such *face* data.

$header[18 .. whatever]$ might also be present; the individual words are simply called $header[18]$, $header[19]$, etc., at the moment.

15. Next comes the *char_info* array, which contains one *char_info_word* per character. Each *char_info_word* contains six fields packed into four bytes as follows.

first byte: *width_index* (8 bits)
second byte: *height_index* (4 bits) times 16, plus *depth_index* (4 bits)
third byte: *italic_index* (6 bits) times 4, plus *tag* (2 bits)
fourth byte: *remainder* (8 bits)

The actual width of a character is *width*[*width_index*], in design-size units; this is a device for compressing information, since many characters have the same width. Since it is quite common for many characters to have the same height, depth, or italic correction, the TFM format imposes a limit of 16 different heights, 16 different depths, and 64 different italic corrections.

Incidentally, the relation $width[0] = height[0] = depth[0] = italic[0] = 0$ should always hold, so that an index of zero implies a value of zero. The *width_index* should never be zero unless the character does not exist in the font, since a character is valid if and only if it lies between *bc* and *ec* and has a nonzero *width_index*.

16. The *tag* field in a *char_info_word* has four values that explain how to interpret the *remainder* field.

$tag = 0$ (*no_tag*) means that *remainder* is unused.
$tag = 1$ (*lig_tag*) means that this character has a ligature/kerning program starting at *lig_kern*[*remainder*].
$tag = 2$ (*list_tag*) means that this character is part of a chain of characters of ascending sizes, and not the largest in the chain. The *remainder* field gives the character code of the next larger character.
$tag = 3$ (*ext_tag*) means that this character code represents an extensible character, i.e., a character that is built up of smaller pieces so that it can be made arbitrarily large. The pieces are specified in *exten*[*remainder*].

define *no_tag* = 0   { vanilla character }
define *lig_tag* = 1   { character has a ligature/kerning program }
define *list_tag* = 2   { character has a successor in a charlist }
define *ext_tag* = 3   { character is extensible }

17.   The *lig_kern* array contains instructions in a simple programming language that explains what to do for special letter pairs. Each word is a *lig_kern_command* of four bytes.

first byte: *skip_byte*, indicates that this is the final program step if the byte is 128 or more, otherwise the next step is obtained by skipping this number of intervening steps.

second byte: *next_char*, "if *next_char* follows the current character, then perform the operation and stop, otherwise continue."

third byte: *op_byte*, indicates a ligature step if less than 128, a kern step otherwise.

fourth byte: *remainder*.

In a kern step, an additional space equal to $kern[256 * (op\_byte - 128) + remainder]$ is inserted between the current character and *next_char*. This amount is often negative, so that the characters are brought closer together by kerning; but it might be positive.

There are eight kinds of ligature steps, having *op_byte* codes $4a+2b+c$ where $0 \le a \le b+c$ and $0 \le b, c \le 1$. The character whose code is *remainder* is inserted between the current character and *next_char*; then the current character is deleted if $b = 0$, and *next_char* is deleted if $c = 0$; then we pass over a characters to reach the next current character (which may have a ligature/kerning program of its own).

Notice that if $a = 0$ and $b = 1$, the current character is unchanged; if $a = b$ and $c = 1$, the current character is changed but the next character is unchanged. VFtoVP will check to see that infinite loops are avoided.

If the very first instruction of the *lig_kern* array has *skip_byte* = 255, the *next_char* byte is the so-called right boundary character of this font; the value of *next_char* need not lie between *bc* and *ec*. If the very last instruction of the *lig_kern* array has *skip_byte* = 255, there is a special ligature/kerning program for a left boundary character, beginning at location $256 * op\_byte + remainder$. The interpretation is that TEX puts implicit boundary characters before and after each consecutive string of characters from the same font. These implicit characters do not appear in the output, but they can affect ligatures and kerning.

If the very first instruction of a character's *lig_kern* program has *skip_byte* > 128, the program actually begins in location $256 * op\_byte + remainder$. This feature allows access to large *lig_kern* arrays, because the first instruction must otherwise appear in a location ≤ 255.

Any instruction with *skip_byte* > 128 in the *lig_kern* array must have $256 * op\_byte + remainder < nl$. If such an instruction is encountered during normal program execution, it denotes an unconditional halt; no ligature command is performed.

define *stop_flag* = 128   { value indicating 'STOP' in a lig/kern program }
define *kern_flag* = 128   { op code for a kern step }

18.   Extensible characters are specified by an *extensible_recipe*, which consists of four bytes called *top*, *mid*, *bot*, and *rep* (in this order). These bytes are the character codes of individual pieces used to build up a large symbol. If *top*, *mid*, or *bot* are zero, they are not present in the built-up result. For example, an extensible vertical line is like an extensible bracket, except that the top and bottom pieces are missing.

19.   The final portion of a `TFM` file is the *param* array, which is another sequence of *fix_word* values.

param[1] = *slant* is the amount of italic slant, which is used to help position accents. For example, *slant* = .25 means that when you go up one unit, you also go .25 units to the right. The *slant* is a pure number; it's the only *fix_word* other than the design size itself that is not scaled by the design size.

param[2] = *space* is the normal spacing between words in text. Note that character "␣" in the font need not have anything to do with blank spaces.

param[3] = *space_stretch* is the amount of glue stretching between words.

param[4] = *space_shrink* is the amount of glue shrinking between words.

param[5] = *x_height* is the height of letters for which accents don't have to be raised or lowered.

param[6] = *quad* is the size of one em in the font.

param[7] = *extra_space* is the amount added to *param*[2] at the ends of sentences.

When the character coding scheme is `TeX math symbols`, the font is supposed to have 15 additional parameters called *num1*, *num2*, *num3*, *denom1*, *denom2*, *sup1*, *sup2*, *sup3*, *sub1*, *sub2*, *supdrop*, *subdrop*, *delim1*, *delim2*, and *axis_height*, respectively. When the character coding scheme is `TeX math extension`, the font is supposed to have six additional parameters called *default_rule_thickness* and *big_op_spacing1* through *big_op_spacing5*.

20.   So that is what `TFM` files hold. The next question is, "What about `VPL` files?" A complete answer to that question appears in the documentation of the companion program, `VPtoVF`, so it will not be repeated here. Suffice it to say that a `VPL` file is an ordinary Pascal text file, and that the output of `VFtoVP` uses only a subset of the possible constructions that might appear in a `VPL` file. Furthermore, hardly anybody really wants to look at the formal definition of `VPL` format, because it is almost self-explanatory when you see an example or two.

⟨ Globals in the outer block 7 ⟩ +≡
vpl_file : *text* ;

21.   ⟨ Set initial values 11 ⟩ +≡
  rewrite(*vpl_file*);

22.   Unpacking the TFM file.   The first thing VFtoVP does is read the entire *tfm_file* into an array of bytes, *tfm*[0 .. (4 * *lf* − 1)].

⟨ Types in the outer block 5 ⟩ +≡
  index = 0 .. *tfm_size*;   { address of a byte in *tfm* }

23.   ⟨ Globals in the outer block 7 ⟩ +≡
tfm: **array** [−1000 .. *tfm_size*] **of** *byte*;   { the TFM input data all goes here }
      { the negative addresses avoid range checks for invalid characters }

24.   The input may, of course, be all screwed up and not a TFM file at all. So we begin cautiously.

  define *abort*(#) ≡
          begin *print_ln*(#);
          print_ln(´Sorry,␣but␣I␣can´´t␣go␣on;␣are␣you␣sure␣this␣is␣a␣TFM?´); **goto** *final_end*;
          end
⟨ Read the whole TFM file 24 ⟩ ≡
  read(*tfm_file*, *tfm*[0]);
  if *tfm*[0] > 127 **then** *abort*(´The␣first␣byte␣of␣the␣input␣file␣exceeds␣127!´);
  if *eof*(*tfm_file*) **then** *abort*(´The␣input␣file␣is␣only␣one␣byte␣long!´);
  read(*tfm_file*, *tfm*[1]); *lf* ← *tfm*[0] * ´400 + *tfm*[1];
  if *lf* = 0 **then** *abort*(´The␣file␣claims␣to␣have␣length␣zero,␣but␣that´´s␣impossible!´);
  if 4 * *lf* − 1 > *tfm_size* **then** *abort*(´The␣file␣is␣bigger␣than␣I␣can␣handle!´);
  for *tfm_ptr* ← 2 **to** 4 * *lf* − 1 **do**
    begin if *eof*(*tfm_file*) **then** *abort*(´The␣file␣has␣fewer␣bytes␣than␣it␣claims!´);
    read(*tfm_file*, *tfm*[*tfm_ptr*]);
    end;
  if ¬*eof*(*tfm_file*) **then**
    begin *print_ln*(´There´´s␣some␣extra␣junk␣at␣the␣end␣of␣the␣TFM␣file,´);
    print_ln(´but␣I´´ll␣proceed␣as␣if␣it␣weren´´t␣there.´);
    end
This code is used in section 131.

25.   After the file has been read successfully, we look at the subfile sizes to see if they check out.

> **define** *eval_two_bytes*(#) ≡
>> **begin if** *tfm*[*tfm_ptr*] > 127 **then** *abort*(´One␣of␣the␣subfile␣sizes␣is␣negative!´);
>> # ← *tfm*[*tfm_ptr*] * ´400 + *tfm*[*tfm_ptr* + 1]; *tfm_ptr* ← *tfm_ptr* + 2;
>> **end**

⟨Set subfile sizes *lh*, *bc*, ..., *np* 25⟩ ≡
  begin *tfm_ptr* ← 2;
  eval_two_bytes(*lh*); *eval_two_bytes*(*bc*); *eval_two_bytes*(*ec*); *eval_two_bytes*(*nw*); *eval_two_bytes*(*nh*);
  eval_two_bytes(*nd*); *eval_two_bytes*(*ni*); *eval_two_bytes*(*nl*); *eval_two_bytes*(*nk*); *eval_two_bytes*(*ne*);
  eval_two_bytes(*np*);
  if *lh* < 2 **then** *abort*(´The␣header␣length␣is␣only␣´, *lh* : 1, ´!´);
  if *nl* > *lig_size* **then** *abort*(´The␣lig/kern␣program␣is␣longer␣than␣I␣can␣handle!´);
  if (*bc* > *ec* + 1) ∨ (*ec* > 255) **then**
    abort(´The␣character␣code␣range␣´, *bc* : 1, ´..´, *ec* : 1, ´␣is␣illegal!´);
  if (*nw* = 0) ∨ (*nh* = 0) ∨ (*nd* = 0) ∨ (*ni* = 0) **then**
    abort(´Incomplete␣subfiles␣for␣character␣dimensions!´);
  if *ne* > 256 **then** *abort*(´There␣are␣´, *ne* : 1, ´␣extensible␣recipes!´);
  if *lf* ≠ 6 + *lh* + (*ec* − *bc* + 1) + *nw* + *nh* + *nd* + *ni* + *nl* + *nk* + *ne* + *np* **then**
    abort(´Subfile␣sizes␣don´´t␣add␣up␣to␣the␣stated␣total!´);
  end

This code is used in section 131.

26.   Once the input data successfully passes these basic checks, VFtoVP believes that it is a TFM file, and the conversion to VPL format will take place. Access to the various subfiles is facilitated by computing the following base addresses. For example, the *char_info* for character *c* will start in location 4 ∗ (*char_base* + *c*) of the *tfm* array.

⟨Globals in the outer block 7⟩ +≡
char_base, *width_base*, *height_base*, *depth_base*, *italic_base*, *lig_kern_base*, *kern_base*, *exten_base*, *param_base*:
    integer;   { base addresses for the subfiles }

27.   ⟨Compute the base addresses 27⟩ ≡
  begin *char_base* ← 6 + *lh* − *bc*; *width_base* ← *char_base* + *ec* + 1; *height_base* ← *width_base* + *nw*;
  depth_base ← *height_base* + *nh*; *italic_base* ← *depth_base* + *nd*; *lig_kern_base* ← *italic_base* + *ni*;
  kern_base ← *lig_kern_base* + *nl*; *exten_base* ← *kern_base* + *nk*; *param_base* ← *exten_base* + *ne* − 1;
  end

This code is used in section 131.

28.   Of course we want to define macros that suppress the detail of how the font information is actually encoded. Each word will be referred to by the *tfm* index of its first byte. For example, if *c* is a character code between *bc* and *ec*, then *tfm*[*char_info*(*c*)] will be the first byte of its *char_info*, i.e., the *width_index*; furthermore *width*(*c*) will point to the *fix_word* for *c*'s width.

> **define** *check_sum* = 24
> **define** *design_size* = *check_sum* + 4
> **define** *scheme* = *design_size* + 4
> **define** *family* = *scheme* + 40
> **define** *random_word* = *family* + 20
> **define** *char_info*(#) ≡ 4 ∗ (*char_base* + #)
> **define** *width_index*(#) ≡ *tfm*[*char_info*(#)]
> **define** *nonexistent*(#) ≡ ((# < *bc*) ∨ (# > *ec*) ∨ (*width_index*(#) = 0))
> **define** *height_index*(#) ≡ (*tfm*[*char_info*(#) + 1] **div** 16)
> **define** *depth_index*(#) ≡ (*tfm*[*char_info*(#) + 1] **mod** 16)
> **define** *italic_index*(#) ≡ (*tfm*[*char_info*(#) + 2] **div** 4)
> **define** *tag*(#) ≡ (*tfm*[*char_info*(#) + 2] **mod** 4)
> **define** *reset_tag*(#) ≡ *tfm*[*char_info*(#) + 2] ← 4 ∗ *italic_index*(#) + *no_tag*
> **define** *remainder*(#) ≡ *tfm*[*char_info*(#) + 3]
> **define** *width*(#) ≡ 4 ∗ (*width_base* + *width_index*(#))
> **define** *height*(#) ≡ 4 ∗ (*height_base* + *height_index*(#))
> **define** *depth*(#) ≡ 4 ∗ (*depth_base* + *depth_index*(#))
> **define** *italic*(#) ≡ 4 ∗ (*italic_base* + *italic_index*(#))
> **define** *exten*(#) ≡ 4 ∗ (*exten_base* + *remainder*(#))
> **define** *lig_step*(#) ≡ 4 ∗ (*lig_kern_base* + (#))
> **define** *kern*(#) ≡ 4 ∗ (*kern_base* + #)   { here # is an index, not a character }
> **define** *param*(#) ≡ 4 ∗ (*param_base* + #)   { likewise }

29.   One of the things we would like to do is take cognizance of fonts whose character coding scheme is `TeX math symbols` or `TeX math extension`; we will set the *font_type* variable to one of the three choices *vanilla*, *mathsy*, or *mathex*.

> **define** *vanilla* = 0   { not a special scheme }
> **define** *mathsy* = 1   { `TeX math symbols` scheme }
> **define** *mathex* = 2   { `TeX math extension` scheme }

⟨ Globals in the outer block 7 ⟩ +≡
font_type: *vanilla* .. *mathex*;   { is this font special? }

30. Unpacking the VF file.   Once the TFM file has been brought into memory, VFtoVP completes the input phase by reading the VF information into another array of bytes. In this case we don't store all the data; we check the redundant bytes for consistency with their TFM counterparts, and we partially decode the packets.

⟨ Globals in the outer block 7 ⟩ +≡
vf : **array** $[0 \mathbin{..} \mathit{vf\_size}]$ **of** *byte*;   { the VF input data goes here }
font_number: **array** $[0 \mathbin{..} \mathit{max\_fonts}]$ **of** *integer*;   { local font numbers }
font_start, *font_chars*: **array** $[0 \mathbin{..} \mathit{max\_fonts}]$ **of** $0 \mathbin{..} \mathit{vf\_size}$;   { font info }
font_ptr: $0 \mathbin{..} \mathit{max\_fonts}$;   { number of local fonts }
packet_start, *packet_end*: **array** $[\mathit{byte}]$ **of** $0 \mathbin{..} \mathit{vf\_size}$;   { character packet boundaries }
packet_found: *boolean*;   { at least one packet has appeared }
temp_byte: *byte*; *count*: *integer*;   { registers for simple calculations }
real_dsize: *real*;   { the design size, converted to floating point }
pl: *integer*;   { packet length }
vf_ptr: $0 \mathbin{..} \mathit{vf\_size}$;   { first unused location in *vf* }
vf_count: *integer*;   { number of bytes read from *vf_file* }

31.   Again we cautiously verify that we've been given decent data.

  define *read_vf* (#) ≡ *read* (*vf_file*, #)
  define *vf_abort* (#) ≡
          begin *print_ln* (#); *print_ln* (´Sorry,␣but␣I␣can´´t␣go␣on;␣are␣you␣sure␣this␣is␣a␣VF?´);
          goto *final_end*;
          end

⟨ Read the whole VF file 31 ⟩ ≡
  read_vf (*temp_byte*);
  if *temp_byte* ≠ *pre* **then** *vf_abort* (´The␣first␣byte␣isn´´t␣`pre´´!´);
  ⟨ Read the preamble command 32 ⟩;
  ⟨ Read and store the font definitions and character packets 33 ⟩;
  ⟨ Read and verify the postamble 34 ⟩
This code is used in section 131.

32.   define $vf\_store(\#) \equiv$
    if $vf\_ptr + \# \geq vf\_size$ then $vf\_abort(\texttt{´The␣file␣is␣bigger␣than␣I␣can␣handle!´})$;
    for $k \leftarrow vf\_ptr$ to $vf\_ptr + \# - 1$ do
      begin if $eof(vf\_file)$ then $vf\_abort(\texttt{´The␣file␣ended␣prematurely!´})$;
      $read\_vf(vf[k])$;
      end;
    $vf\_count \leftarrow vf\_count + \#$; $vf\_ptr \leftarrow vf\_ptr + \#$

⟨ Read the preamble command 32 ⟩ ≡
  if $eof(vf\_file)$ then $vf\_abort(\texttt{´The␣input␣file␣is␣only␣one␣byte␣long!´})$;
  $read\_vf(temp\_byte)$;
  if $temp\_byte \neq id\_byte$ then $vf\_abort(\texttt{´Wrong␣VF␣version␣number␣in␣second␣byte!´})$;
  if $eof(vf\_file)$ then $vf\_abort(\texttt{´The␣input␣file␣is␣only␣two␣bytes␣long!´})$;
  $read\_vf(temp\_byte)$;   { read the length of introductory comment }
  $vf\_count \leftarrow 11$; $vf\_ptr \leftarrow 0$; $vf\_store(temp\_byte)$;
  for $k \leftarrow 0$ to $vf\_ptr - 1$ do $print(xchr[vf[k]])$;

    end;
  $real\_dsize \leftarrow (((tfm[design\_size] * 256 + tfm[design\_size + 1]) * 256 + tfm[design\_size + 2]) * 256 +$
      $tfm[design\_size + 3]) / \texttt{´4000000}$;
  if $count \neq 8$ then
    begin $print\_ln(\texttt{´Check␣sum␣and/or␣design␣size␣mismatch.´})$;
    $print\_ln(\texttt{´Data␣from␣TFM␣file␣will␣be␣assumed␣correct.´})$;
    end

This code is used in section 31.

33.   ⟨ Read and store the font definitions and character packets 33 ⟩ ≡
  for $k \leftarrow 0$ to 255 do $packet\_start[k] \leftarrow vf\_size$;
  $font\_ptr \leftarrow 0$; $packet\_found \leftarrow false$; $font\_start[0] \leftarrow vf\_ptr$;
  repeat if $eof(vf\_file)$ then
      begin $print\_ln(\texttt{´File␣ended␣without␣a␣postamble!´})$; $temp\_byte \leftarrow post$;
      end
    else begin $read\_vf(temp\_byte)$; $incr(vf\_count)$;
      if $temp\_byte \neq post$ then
        if $temp\_byte > long\_char$ then ⟨ Read and store a font definition 35 ⟩
        else ⟨ Read and store a character packet 46 ⟩;
      end;
  until $temp\_byte = post$

This code is used in section 31.

34. ⟨ Read and verify the postamble 34 ⟩ ≡
  while $(temp\_byte = post) \land \neg eof(vf\_file)$ **do**
    begin $read\_vf(temp\_byte)$; $incr(vf\_count)$;
    end;
  if $\neg eof(vf\_file)$ **then**
    begin $print\_ln($ ´There´´s␣some␣extra␣junk␣at␣the␣end␣of␣the␣VF␣file.´ $)$;
    $print\_ln($ ´I´´ll␣proceed␣as␣if␣it␣weren´´t␣there.´ $)$;
    end;
  if $vf\_count \bmod 4 \neq 0$ **then** $print\_ln($ ´VF␣data␣not␣a␣multiple␣of␣4␣bytes´ $)$
This code is used in section 31.

35.   ⟨ Read and store a font definition 35 ⟩ ≡
  begin if $packet\_found \lor (temp\_byte \geq pre)$ **then**
    $vf\_abort($ ´Illegal␣byte␣´, $temp\_byte : 1,$ ´␣at␣beginning␣of␣character␣packet!´ $)$;
  $font\_number[font\_ptr] \leftarrow vf\_read(temp\_byte - fnt\_def1 + 1)$;
  if $font\_ptr = max\_fonts$ **then** $vf\_abort($ ´I␣can´´t␣handle␣that␣many␣fonts!´ $)$;
  $vf\_store(14)$;   { $c[4]$ $s[4]$ $d[4]$ $a[1]$ $l[1]$ }
  if $vf[vf\_ptr - 10] > 0$ **then**   { s is negative or exceeds $2^{24} - 1$ }
    $vf\_abort($ ´Mapped␣font␣size␣is␣too␣big!´ $)$;
  $a \leftarrow vf[vf\_ptr - 2]$; $l \leftarrow vf[vf\_ptr - 1]$; $vf\_store(a + l)$;   { $n[a + l]$ }
  ⟨ Print the name of the local font 36 ⟩;
  ⟨ Read the local font's TFM file and record the characters it contains 39 ⟩;
  $incr(font\_ptr)$; $font\_start[font\_ptr] \leftarrow vf\_ptr$;
  end
This code is used in section 33.

36.   The font area may need to be separated from the font name on some systems. Here we simply reproduce the font area and font name (with no space or punctuation between them).

⟨ Print the name of the local font 36 ⟩ ≡
  $print($ ´MAPFONT␣´, $font\_ptr : 1,$ ´:␣´ $)$;
  for $k \leftarrow font\_start[font\_ptr] + 14$ **to** $vf\_ptr - 1$ **do** $print(xchr[vf[k]])$;
  $k \leftarrow font\_start[font\_ptr] + 5$;
  $print\_ln($ ´␣at␣´, $(((vf[k] * 256 + vf[k + 1]) * 256 + vf[k + 2]) / ´4000000) * real\_dsize : 2 : 2,$ ´pt´ $)$
This code is used in section 35.

37.   Now we must read in another TFM file. But this time we needn't be so careful, because we merely want to discover which characters are present. The next few sections of the program are copied pretty much verbatim from DVItype, so that system-dependent modifications can be copied from existing software.
  It turns out to be convenient to read four bytes at a time, when we are inputting from the local TFM files. The input goes into global variables $b0$, $b1$, $b2$, and $b3$, with $b0$ getting the first byte and $b3$ the fourth.

⟨ Globals in the outer block 7 ⟩ +≡
a: *integer*;   { length of the area/directory spec }
l: *integer*;   { length of the font name proper }
cur_name: **packed array** $[1 .. name\_length]$ **of** *char*;   { external name, with no lower case letters }
$b0, b1, b2, b3$: *byte*;   { four bytes input at once }
$font\_lh$: $0 .. ´77777$;   { header length of current local font }
$font\_bc, font\_ec$: $0 .. ´77777$;   { character range of current local font }

38.   The *read_tfm_word* procedure sets *b0* through *b3* to the next four bytes in the current TFM file.

> **define** *read_tfm*(#) ≡
>   **if** *eof*(*tfm_file*) **then** # ← 0 **else** *read*(*tfm_file*, #)

procedure *read_tfm_word*;
  begin *read_tfm*(*b0*); *read_tfm*(*b1*); *read_tfm*(*b2*); *read_tfm*(*b3*);
  end;

39.   We use the *vf* array to store a list of all valid characters in the local font, beginning at location *font_chars*[*f*].

⟨ Read the local font's TFM file and record the characters it contains 39 ⟩ ≡
  font_chars[*font_ptr*] ← *vf_ptr*; ⟨ Move font name into the *cur_name* string 44 ⟩;
  reset(*tfm_file*, *cur_name*);
  if *eof*(*tfm_file*) **then** *print_ln*(´---not␣loaded,␣TFM␣file␣can´´t␣be␣opened!´)
  else begin *font_bc* ← 0; *font_ec* ← 256;   { will cause error if not modified soon }
    read_tfm_word;
    if *b2* < 128 **then**
      begin *font_lh* ← *b2* ∗ 256 + *b3*; *read_tfm_word*;
      if (*b0* < 128) ∧ (*b2* < 128) **then**
        begin *font_bc* ← *b0* ∗ 256 + *b1*; *font_ec* ← *b2* ∗ 256 + *b3*;
        end;
      end;
    if *font_bc* ≤ *font_ec* **then**
      if *font_ec* > 255 **then** *print_ln*(´---not␣loaded,␣bad␣TFM␣file!´)
      else begin for *k* ← 0 **to** 3 + *font_lh* **do**
          begin *read_tfm_word*;
          if *k* = 4 **then** ⟨ Check the check sum 40 ⟩;
          if *k* = 5 **then** ⟨ Check the design size 41 ⟩;
          end;
        for *k* ← *font_bc* **to** *font_ec* **do**
          begin *read_tfm_word*;
          if *b0* > 0 **then**   { character *k* exists in the font }
            begin *vf*[*vf_ptr*] ← *k*; *incr*(*vf_ptr*);
            if *vf_ptr* = *vf_size* **then** *vf_abort*(´I´´m␣out␣of␣VF␣memory!´);
            end;
          end;
        end;
    if *eof*(*tfm_file*) **then** *print_ln*(´---trouble␣is␣brewing,␣TFM␣file␣ended␣too␣soon!´);
    end;
  incr(*vf_ptr*)   { leave space for character search later }
This code is used in section 35.

40.   ⟨ Check the check sum 40 ⟩ ≡
  if *b0* + *b1* + *b2* + *b3* > 0 **then**
    if (*b0* ≠ *vf*[*font_start*[*font_ptr*]]) ∨ (*b1* ≠ *vf*[*font_start*[*font_ptr*] + 1]) ∨
          (*b2* ≠ *vf*[*font_start*[*font_ptr*] + 2]) ∨ (*b3* ≠ *vf*[*font_start*[*font_ptr*] + 3]) **then**
      begin *print_ln*(´Check␣sum␣in␣VF␣file␣being␣replaced␣by␣TFM␣check␣sum´);
      vf[*font_start*[*font_ptr*]] ← *b0*; *vf*[*font_start*[*font_ptr*] + 1] ← *b1*; *vf*[*font_start*[*font_ptr*] + 2] ← *b2*;
      vf[*font_start*[*font_ptr*] + 3] ← *b3*;
      end
This code is used in section 39.

41. ⟨Check the design size 41⟩ ≡
  if $(b0 \neq \mathit{vf}[\mathit{font\_start}[\mathit{font\_ptr}] + 8]) \vee (b1 \neq \mathit{vf}[\mathit{font\_start}[\mathit{font\_ptr}] + 9]) \vee$
      $(b2 \neq \mathit{vf}[\mathit{font\_start}[\mathit{font\_ptr}] + 10]) \vee (b3 \neq \mathit{vf}[\mathit{font\_start}[\mathit{font\_ptr}] + 11])$ **then**
    begin $\mathit{print\_ln}(\text{´Design}_\sqcup\text{size}_\sqcup\text{in}_\sqcup\text{VF}_\sqcup\text{file}_\sqcup\text{being}_\sqcup\text{replaced}_\sqcup\text{by}_\sqcup\text{TFM}_\sqcup\text{design}_\sqcup\text{size´});$
    $\mathit{vf}[\mathit{font\_start}[\mathit{font\_ptr}] + 8] \leftarrow b0;$ $\mathit{vf}[\mathit{font\_start}[\mathit{font\_ptr}] + 9] \leftarrow b1;$ $\mathit{vf}[\mathit{font\_start}[\mathit{font\_ptr}] + 10] \leftarrow b2;$
    $\mathit{vf}[\mathit{font\_start}[\mathit{font\_ptr}] + 11] \leftarrow b3;$
    end

This code is used in section 39.

42. If no font directory has been specified, `DVI`-reading software is supposed to use the default font directory, which is a system-dependent place where the standard fonts are kept. The string variable *default_directory* contains the name of this area.

  define $\mathit{default\_directory\_name} \equiv \text{´TeXfonts:´}$ { change this to the correct name }
  define $\mathit{default\_directory\_name\_length} = 9$ { change this to the correct length }

⟨Globals in the outer block 7⟩ +≡
default_directory: **packed array** $[1 .. \mathit{default\_directory\_name\_length}]$ **of** *char*;

43. ⟨Set initial values 11⟩ +≡
  $\mathit{default\_directory} \leftarrow \mathit{default\_directory\_name};$

44. The string *cur_name* is supposed to be set to the external name of the TFM file for the current font. This usually means that we need to prepend the name of the default directory, and to append the suffix '.TFM'. Furthermore, we change lower case letters to upper case, since *cur_name* is a Pascal string.

⟨Move font name into the *cur_name* string 44⟩ ≡
  for $k \leftarrow 1$ **to** *name_length* **do** $\mathit{cur\_name}[k] \leftarrow \text{´}_\sqcup\text{´};$
  if $a = 0$ **then**
    begin for $k \leftarrow 1$ **to** *default_directory_name_length* **do** $\mathit{cur\_name}[k] \leftarrow \mathit{default\_directory}[k];$
    $r \leftarrow \mathit{default\_directory\_name\_length};$
    end
  else $r \leftarrow 0;$
  for $k \leftarrow \mathit{font\_start}[\mathit{font\_ptr}] + 14$ **to** $\mathit{vf\_ptr} - 1$ **do**
    begin $\mathit{incr}(r);$
    if $r + 4 > \mathit{name\_length}$ **then** $\mathit{vf\_abort}(\text{´Font}_\sqcup\text{name}_\sqcup\text{too}_\sqcup\text{long}_\sqcup\text{for}_\sqcup\text{me!´});$
    if $(\mathit{vf}[k] \geq \texttt{"a"}) \wedge (\mathit{vf}[k] \leq \texttt{"z"})$ **then** $\mathit{cur\_name}[r] \leftarrow \mathit{xchr}[\mathit{vf}[k] - \text{´}40]$
    else $\mathit{cur\_name}[r] \leftarrow \mathit{xchr}[\mathit{vf}[k]];$
    end;
  $\mathit{cur\_name}[r + 1] \leftarrow \text{´.´};$ $\mathit{cur\_name}[r + 2] \leftarrow \text{´T´};$ $\mathit{cur\_name}[r + 3] \leftarrow \text{´F´};$ $\mathit{cur\_name}[r + 4] \leftarrow \text{´M´}$

This code is used in section 39.

45.   It's convenient to have a subroutine that reads a k-byte number from *vf_file*.

> **define** *get_vf*(#) ≡
> > **if** *eof*(*vf_file*) **then** # ← 0 **else** *read_vf*(#)

function *vf_read*(*k* : *integer*): *integer*;   {actually $1 \leq k \leq 4$}
>   **var** *b*: *byte*;   {input byte}
>   *a*: *integer*;   {accumulator}
>   **begin** *vf_count* ← *vf_count* + *k*; *get_vf*(*b*); *a* ← *b*;
>   **if** $k = 4$ **then**
>   **if** $b \geq 128$ **then** *a* ← *a* − 256;   {4-byte numbers are signed}
>   **while** $k > 1$ **do**
>   **begin** *get_vf*(*b*); *a* ← 256 ∗ *a* + *b*; *decr*(*k*);
>   **end**;
>   *vf_read* ← *a*;
>   **end**;

46.   The VF format supports arbitrary 4-byte character codes, but VPL format presently does not. Therefore we give up if the character code is not between 0 and 255.

After more experience is gained with present-day VPL files, the best way to extend them to arbitrary character codes will become clear; the extensions to VFtoVP and VPtoVF should not be difficult.

⟨Read and store a character packet 46⟩ ≡
>   **begin if** *temp_byte* = *long_char* **then**
>   **begin** *pl* ← *vf_read*(4); *c* ← *vf_read*(4); *count* ← *vf_read*(4);   {*pl*[4] *cc*[4] *tfm*[4]}
>   **end**
>   **else begin** *pl* ← *temp_byte*; *c* ← *vf_read*(1); *count* ← *vf_read*(3);   {*pl*[1] *cc*[1] *tfm*[3]}
>   **end**;
>   **if** *nonexistent*(*c*) **then** *vf_abort*(´Character␣´, *c* : 1, ´␣does␣not␣exist!´);
>   **if** *packet_start*[*c*] < *vf_size* **then** *print_ln*(´Discarding␣earlier␣packet␣for␣character␣´, *c* : 1);
>   **if** *count* ≠ *tfm_width*(*c*) **then**
>   *print_ln*(´Incorrect␣TFM␣width␣for␣character␣´, *c* : 1, ´␣in␣VF␣file´);
>   **if** *pl* < 0 **then** *vf_abort*(´Negative␣packet␣length!´);
>   *packet_start*[*c*] ← *vf_ptr*; *vf_store*(*pl*); *packet_end*[*c*] ← *vf_ptr* − 1; *packet_found* ← *true*;
>   **end**

This code is used in section 33.

47.   The preceding code requires a simple subroutine that evaluates TFM data.

function *tfm_width*(*c* : *byte*): *integer*;
>   **var** *a*: *integer*;   {accumulator}
>   *k*: *index*;   {index into *tfm*}
>   **begin** *k* ← *width*(*c*);   {we assume that character *c* exists}
>   *a* ← *tfm*[*k*];
>   **if** $a \geq 128$ **then** *a* ← *a* − 256;
>   *tfm_width* ← ((256 ∗ *a* + *tfm*[*k* + 1]) ∗ 256 + *tfm*[*k* + 2]) ∗ 256 + *tfm*[*k* + 3];
>   **end**;

48. Basic output subroutines.   Let us now define some procedures that will reduce the rest of VFtoVP's
work to a triviality.

First of all, it is convenient to have an abbreviation for output to the VPL file:

define $out(\#) \equiv write(vpl\_file, \#)$

49.   In order to stick to standard Pascal, we use an $xchr$ array to do appropriate conversion of ASCII codes.
Three other little strings are used to produce $face$ codes like MIE.

⟨ Globals in the outer block 7 ⟩ +≡
$ASCII\_04$, $ASCII\_10$, $ASCII\_14$: **packed array** $[1 .. 32]$ **of** $char$;
        { strings for output in the user's external character set }
$xchr$: **packed array** $[0 .. 255]$ **of** $char$;
MBL_string, RI_string, RCE_string: **packed array** $[1 .. 3]$ **of** $char$;
        { handy string constants for $face$ codes }

50.   ⟨ Set initial values 11 ⟩ +≡
  $ASCII\_04 \leftarrow$ ´␣!"#$%&´´()*+,-./0123456789:;<=>?´;
  $ASCII\_10 \leftarrow$ ´@ABCDEFGHIJKLMNOPQRSTUVWXYZ[\]^_´;
  $ASCII\_14 \leftarrow$ ´`abcdefghijklmnopqrstuvwxyz{|}~?´;
  for $k \leftarrow 0$ **to** 255 **do** $xchr[k] \leftarrow$ ´?´;
  for $k \leftarrow 0$ **to** ´37 **do**
    begin $xchr[k + ´40] \leftarrow ASCII\_04[k+1]$; $xchr[k + ´100] \leftarrow ASCII\_10[k+1]$;
    $xchr[k + ´140] \leftarrow ASCII\_14[k+1]$;
    end;
  $MBL\_string \leftarrow$ ´MBL´; $RI\_string \leftarrow$ ´RI␣´; $RCE\_string \leftarrow$ ´RCE´;

51.   The array dig will hold a sequence of digits to be output.

⟨ Globals in the outer block 7 ⟩ +≡
dig: **array** $[0 .. 11]$ **of** $0 .. 9$;

52.   Here, in fact, are two procedures that output $dig[j-1] \ldots dig[0]$, given $j > 0$.

procedure $out\_digs(j : integer)$;   { outputs j digits }
  begin repeat $decr(j)$; $out(dig[j] : 1)$;
  until $j = 0$;
  end;

procedure $print\_digs(j : integer)$;   { prints j digits }
  begin repeat $decr(j)$; $print(dig[j] : 1)$;
  until $j = 0$;
  end;

53.   The $print\_octal$ procedure indicates how $print\_digs$ can be used. Since this procedure is used only to
print character codes, it always produces three digits.

procedure $print\_octal(c : byte)$;   { prints octal value of c }
  var j: $0 .. 2$;   { index into dig }
  begin $print(´´´´)$;   { an apostrophe indicates the octal notation }
  for $j \leftarrow 0$ **to** 2 **do**
    begin $dig[j] \leftarrow c$ **mod** 8; $c \leftarrow c$ **div** 8;
    end;
  $print\_digs(3)$;
  end;

54. A `VPL` file has nested parentheses, and we want to format the output so that its structure is clear. The *level* variable keeps track of the depth of nesting.

⟨ Globals in the outer block 7 ⟩ +≡
level: 0 . . 5;

55. ⟨ Set initial values 11 ⟩ +≡
  level ← 0;

56. Three simple procedures suffice to produce the desired structure in the output.

procedure *out_ln*; { finishes one line, indents the next }
  var *l*: 0 . . 5;
  begin *write_ln*(*vpl_file*);
  for *l* ← 1 **to** *level* **do** *out*(´␣␣␣´);
  end;

procedure *left*; { outputs a left parenthesis }
  begin *incr*(*level*); *out*(´(´);
  end;

procedure *right*; { outputs a right parenthesis and finishes a line }
  begin *decr*(*level*); *out*(´)´); *out_ln*;
  end;

57. The value associated with a property can be output in a variety of ways. For example, we might want to output a BCPL string that begins in *tfm*[*k*]:

procedure *out_BCPL*(*k* : *index*); { outputs a string, preceded by a blank space }
  var *l*: 0 . . 39; { the number of bytes remaining }
  begin *out*(´␣´); *l* ← *tfm*[*k*];
  while *l* > 0 **do**
    begin *incr*(*k*); *decr*(*l*); *out*(*xchr*[*tfm*[*k*]]);
    end;
  end;

58. The property value might also be a sequence of *l* bytes, beginning in *tfm*[*k*], that we would like to output in octal notation. The following procedure assumes that $l \leq 4$, but larger values of *l* could be handled easily by enlarging the *dig* array and increasing the upper bounds on *b* and *j*.

procedure *out_octal*(*k*, *l* : *index*); { outputs *l* bytes in octal }
  var *a*: 0 . . ´1777; { accumulator for bits not yet output }
    b: 0 . . 32; { the number of significant bits in *a* }
    j: 0 . . 11; { the number of digits of output }
  begin *out*(´␣O␣´); { specify octal format }
  a ← 0; *b* ← 0; *j* ← 0;
  while *l* > 0 **do** ⟨ Reduce *l* by one, preserving the invariants 59 ⟩;
  while (*a* > 0) ∨ (*j* = 0) **do**
    begin *dig*[*j*] ← *a* **mod** 8; *a* ← *a* **div** 8; *incr*(*j*);
    end;
  out_digs(*j*);
  end;

59. ⟨Reduce l by one, preserving the invariants 59⟩ ≡
 begin $decr(l)$;
 if $tfm[k+l] \neq 0$ **then**
  begin while $b > 2$ **do**
   begin $dig[j] \leftarrow a \bmod 8$; $a \leftarrow a \textbf{ div } 8$; $b \leftarrow b - 3$; $incr(j)$;
   end;
  case b **of**
  0: $a \leftarrow tfm[k+l]$;
  1: $a \leftarrow a + 2 * tfm[k+l]$;
  2: $a \leftarrow a + 4 * tfm[k+l]$;
  end;
  end;
 $b \leftarrow b + 8$;
 end

This code is used in section 58.

60. The property value may be a character, which is output in octal unless it is a letter or a digit.

procedure $out\_char(c : byte)$;   {outputs a character}
 begin if $font\_type > vanilla$ **then**
  begin $tfm[0] \leftarrow c$; $out\_octal(0, 1)$
  end
 else if $((c \geq \texttt{"0"}) \wedge (c \leq \texttt{"9"})) \vee ((c \geq \texttt{"A"}) \wedge (c \leq \texttt{"Z"})) \vee ((c \geq \texttt{"a"}) \wedge (c \leq \texttt{"z"}))$ **then**
   $out(\texttt{´␣C␣´}, xchr[c])$
  else begin $tfm[0] \leftarrow c$; $out\_octal(0, 1)$;
   end;
 end;

61. The property value might be a "face" byte, which is output in the curious code mentioned earlier, provided that it is less than 18.

procedure $out\_face(k : index)$;   {outputs a $face$}
 var s: $0 \ldots 1$;   {the slope}
  b: $0 \ldots 8$;   {the weight and expansion}
 begin if $tfm[k] \geq 18$ **then** $out\_octal(k, 1)$
 else begin $out(\texttt{´␣F␣´})$;   {specify face-code format}
  $s \leftarrow tfm[k] \bmod 2$; $b \leftarrow tfm[k] \textbf{ div } 2$; $out(MBL\_string[1 + (b \bmod 3)])$; $out(RI\_string[1 + s])$;
  $out(RCE\_string[1 + (b \textbf{ div } 3)])$;
  end;
 end;

62. And finally, the value might be a *fix_word*, which is output in decimal notation with just enough decimal places for VPtoVF to recover every bit of the given *fix_word*.

All of the numbers involved in the intermediate calculations of this procedure will be nonnegative and less than $10 \cdot 2^{24}$.

procedure *out_fix* (*k* : *index*);   { outputs a *fix_word* }
  var *a*: 0 . . ´7777;   { accumulator for the integer part }
    f: *integer*;   { accumulator for the fraction part }
    j: 0 . . 12;   { index into *dig* }
    delta: *integer*;   { amount if allowable inaccuracy }
  begin *out*(´␣R␣´);   { specify real format }
  a ← (*tfm*[*k*] ∗ 16) + (*tfm*[*k* + 1] **div** 16); *f* ← ((*tfm*[*k* + 1] **mod** 16) ∗ ´400 + *tfm*[*k* + 2]) ∗ ´400 + *tfm*[*k* + 3];
  if *a* > ´3777 **then** ⟨Reduce negative to positive 65⟩;
  ⟨Output the integer part, *a*, in decimal notation 63⟩;
  ⟨Output the fraction part, *f*/2²⁰, in decimal notation 64⟩;
  end;

63. The following code outputs at least one digit even if *a* = 0.

⟨Output the integer part, *a*, in decimal notation 63⟩ ≡
  begin *j* ← 0;
  repeat *dig*[*j*] ← *a* **mod** 10; *a* ← *a* **div** 10; *incr*(*j*);
  until *a* = 0;
  out_digs(*j*);
  end

This code is used in section 62.

64. And the following code outputs at least one digit to the right of the decimal point.

⟨Output the fraction part, *f*/2²⁰, in decimal notation 64⟩ ≡
  begin *out*(´.´); *f* ← 10 ∗ *f* + 5; *delta* ← 10;
  repeat if *delta* > ´4000000 **then** *f* ← *f* + ´2000000 − (*delta* **div** 2);
    out(*f* **div** ´4000000 : 1); *f* ← 10 ∗ (*f* **mod** ´4000000); *delta* ← *delta* ∗ 10;
  until *f* ≤ *delta*;
  end;

This code is used in section 62.

65. ⟨Reduce negative to positive 65⟩ ≡
  begin *out*(´-´); *a* ← ´10000 − *a*;
  if *f* > 0 **then**
    begin *f* ← ´4000000 − *f*; *decr*(*a*);
    end;
  end

This code is used in section 62.

66. Outputting the TFM info.   TEX checks the information of a TFM file for validity as the file is being read in, so that no further checks will be needed when typesetting is going on. And when it finds something wrong, it just calls the file "bad," without identifying the nature of the problem, since TFM files are supposed to be good almost all of the time.

Of course, a bad file shows up every now and again, and that's where VFtoVP comes in. This program wants to catch at least as many errors as TEX does, and to give informative error messages besides. All of the errors are corrected, so that the VPL output will be correct (unless, of course, the TFM file was so loused up that no attempt is being made to fathom it).

67.   Just before each character is processed, its code is printed in octal notation. Up to eight such codes appear on a line; so we have a variable to keep track of how many are currently there. We also keep track of whether or not any errors have had to be corrected.

⟨ Globals in the outer block 7 ⟩ +≡
chars_on_line: 0 . . 8;   { the number of characters printed on the current line }
perfect: *boolean*;   { was the file free of errors? }

68.   ⟨ Set initial values 11 ⟩ +≡
   chars_on_line ← 0;
   perfect ← *true*;   { innocent until proved guilty }

69.   Error messages are given with the help of the *bad* and *range_error* and *bad_char* macros:

   define *bad*(#) ≡
           begin *perfect* ← *false*;
           if *chars_on_line* > 0 **then** *print_ln*(´␣´);
           chars_on_line ← 0; *print_ln*(´Bad␣TFM␣file:␣´, #);
           end
   define *range_error*(#) ≡
           begin *perfect* ← *false*; *print_ln*(´␣´); *print*(#, ´␣index␣for␣character␣´); *print_octal*(c);
           print_ln(´␣is␣too␣large;´); *print_ln*(´so␣I␣reset␣it␣to␣zero.´);
           end
   define *bad_char_tail*(#) ≡ *print_octal*(#); *print_ln*(´.´);
        end
   define *bad_char*(#) ≡
        begin *perfect* ← *false*;
        if *chars_on_line* > 0 **then** *print_ln*(´␣´);
        chars_on_line ← 0; *print*(´Bad␣TFM␣file:␣´, #, ´␣nonexistent␣character␣´); *bad_char_tail*
   define *correct_bad_char_tail*(#) ≡ *print_octal*(*tfm*[#]); *print_ln*(´.´); *tfm*[#] ← *bc*;
        end
   define *correct_bad_char*(#) ≡
        begin *perfect* ← *false*;
        if *chars_on_line* > 0 **then** *print_ln*(´␣´);
        chars_on_line ← 0; *print*(´Bad␣TFM␣file:␣´, #, ´␣nonexistent␣character␣´);
        correct_bad_char_tail
⟨ Globals in the outer block 7 ⟩ +≡
i: 0 . . ´77777;   { an index to words of a subfile }
c: 0 . . 256;   { a random character }
d: 0 . . 3;   { byte number in a word }
k: *index*;   { a random index }
r: 0 . . 65535;   { a random two-byte value }

70.   There are a lot of simple things to do, and they have to be done one at a time, so we might as well get down to business. The first things that VFtoVP will put into the VPL file appear in the header part.

⟨ Do the header 70 ⟩ ≡
  begin *font_type* ← *vanilla*;
  if *lh* ≥ 12 **then**
    begin ⟨ Set the true *font_type* 75 ⟩;
    if *lh* ≥ 17 **then**
      begin ⟨ Output the family name 77 ⟩;
      if *lh* ≥ 18 **then** ⟨ Output the rest of the header 78 ⟩;
      end;
    ⟨ Output the character coding scheme 76 ⟩;
    end;
  ⟨ Output the design size 73 ⟩;
  ⟨ Output the check sum 71 ⟩;
  ⟨ Output the *seven_bit_safe_flag* 79 ⟩;
  end

This code is used in section 132.

71.   ⟨ Output the check sum 71 ⟩ ≡
  left; *out*(´CHECKSUM´); *out_octal*(*check_sum*, 4); *right*
This code is used in section 70.

72.   Incorrect design sizes are changed to 10 points.

  define *bad_design*(#) ≡
          begin *bad*(´Design␣size␣´, #, ´!´); *print_ln*(´I´´ve␣set␣it␣to␣10␣points.´);
          out(´␣D␣10´);
          end

73.   ⟨ Output the design size 73 ⟩ ≡
  left; *out*(´DESIGNSIZE´);
  if *tfm*[*design_size*] > 127 **then** *bad_design*(´negative´)
  else if (*tfm*[*design_size*] = 0) ∧ (*tfm*[*design_size* + 1] < 16) **then** *bad_design*(´too␣small´)
    else *out_fix*(*design_size*);
  right; *out*(´(COMMENT␣DESIGNSIZE␣IS␣IN␣POINTS)´); *out_ln*;
  out(´(COMMENT␣OTHER␣SIZES␣ARE␣MULTIPLES␣OF␣DESIGNSIZE)´); *out_ln*
This code is used in section 70.

74. Since we have to check two different BCPL strings for validity, we might as well write a subroutine to make the check.

procedure *check_BCPL*(*k*, *l* : *index*); { checks a string of length < *l* }
  var *j*: *index*; { runs through the string }
    c: *byte*; { character being checked }
  begin if *tfm*[*k*] ≥ *l* **then**
    begin *bad*(´String␣is␣too␣long;␣I´´ve␣shortened␣it␣drastically.´); *tfm*[*k*] ← 1;
    end;
  for *j* ← *k* + 1 **to** *k* + *tfm*[*k*] **do**
    begin *c* ← *tfm*[*j*];
    if (*c* = "(") ∨ (*c* = ")") **then**
      begin *bad*(´Parenthesis␣in␣string␣has␣been␣changed␣to␣slash.´); *tfm*[*j*] ← "/";
      end
    else if (*c* < "␣") ∨ (*c* > "~") **then**
        begin *bad*(´Nonstandard␣ASCII␣code␣has␣been␣blotted␣out.´); *tfm*[*j*] ← "?";
        end
      else if (*c* ≥ "a") ∧ (*c* ≤ "z") **then** *tfm*[*j*] ← *c* + "A" − "a"; { upper-casify letters }
    end;
  end;

75. The *font_type* starts out *vanilla*; possibly we need to reset it.

⟨ Set the true *font_type* 75 ⟩ ≡
  begin *check_BCPL*(*scheme*, 40);
  if (*tfm*[*scheme*] ≥ 11) ∧ (*tfm*[*scheme* + 1] = "T") ∧ (*tfm*[*scheme* + 2] = "E") ∧ (*tfm*[*scheme* + 3] = "X") ∧
      (*tfm*[*scheme* + 4] = "␣") ∧ (*tfm*[*scheme* + 5] = "M") ∧ (*tfm*[*scheme* + 6] = "A") ∧
      (*tfm*[*scheme* + 7] = "T") ∧ (*tfm*[*scheme* + 8] = "H") ∧ (*tfm*[*scheme* + 9] = "␣") **then**
    begin if (*tfm*[*scheme* + 10] = "S") ∧ (*tfm*[*scheme* + 11] = "Y") **then** *font_type* ← *mathsy*
    else if (*tfm*[*scheme* + 10] = "E") ∧ (*tfm*[*scheme* + 11] = "X") **then** *font_type* ← *mathex*;
    end;
  end

This code is used in section 70.

76. ⟨ Output the character coding scheme 76 ⟩ ≡
  left; *out*(´CODINGSCHEME´); *out_BCPL*(*scheme*); *right*
This code is used in section 70.

77. ⟨ Output the family name 77 ⟩ ≡
  left; *out*(´FAMILY´); *check_BCPL*(*family*, 20); *out_BCPL*(*family*); *right*
This code is used in section 70.

78. ⟨ Output the rest of the header 78 ⟩ ≡
  begin *left*; *out*(´FACE´); *out_face*(*random_word* + 3); *right*;
  for *i* ← 18 **to** *lh* − 1 **do**
    begin *left*; *out*(´HEADER␣D␣´, *i* : 1); *out_octal*(*check_sum* + 4 ∗ *i*, 4); *right*;
    end;
  end

This code is used in section 70.

79.   This program does not check to see if the *seven_bit_safe_flag* has the correct setting, i.e., if it really reflects the seven-bit-safety of the TFM file; the stated value is merely put into the VPL file. The VPtoVF program will store a correct value and give a warning message if a file falsely claims to be safe.

⟨Output the *seven_bit_safe_flag* 79⟩ ≡
  if $(lh > 17) \land (tfm[random\_word] > 127)$ **then**
    begin *left*; *out*(´SEVENBITSAFEFLAG␣TRUE´); *right*;
    end

This code is used in section 70.

80.   The next thing to take care of is the list of parameters.

⟨Do the parameters 80⟩ ≡
  if $np > 0$ **then**
    begin *left*; *out*(´FONTDIMEN´); *out_ln*;
    for $i \leftarrow 1$ **to** np **do** ⟨Check and output the *i*th parameter 82⟩;
    right;
    end;
  ⟨Check to see if *np* is complete for this font type 81⟩;

This code is used in section 132.

81.   ⟨Check to see if *np* is complete for this font type 81⟩ ≡
  if $(font\_type = mathsy) \land (np \neq 22)$ **then**
    print_ln(´Unusual␣number␣of␣fontdimen␣parameters␣for␣a␣math␣symbols␣font␣(´, $np : 1$,
        ´␣not␣22).´)
  else if $(font\_type = mathex) \land (np \neq 13)$ **then**
    print_ln(´Unusual␣number␣of␣fontdimen␣parameters␣for␣an␣extension␣font␣(´, $np : 1$,
        ´␣not␣13).´)

This code is used in section 80.

82.   All *fix_word* values except the design size and the first parameter will be checked to make sure that they are less than 16.0 in magnitude, using the *check_fix* macro:

  define *check_fix_tail*(#) ≡ *bad*(#, ´␣´, $i : 1$, ´␣is␣too␣big;´); *print_ln*(´I␣have␣set␣it␣to␣zero.´);
        end
  define *check_fix*(#) ≡
        if $(tfm[\#] > 0) \land (tfm[\#] < 255)$ **then**
            begin $tfm[\#] \leftarrow 0$; $tfm[(\#) + 1] \leftarrow 0$; $tfm[(\#) + 2] \leftarrow 0$; $tfm[(\#) + 3] \leftarrow 0$; *check_fix_tail*

⟨Check and output the *i*th parameter 82⟩ ≡
  begin *left*;

    for $i \leftarrow 0$ **to** $nk - 1$ **do** $\textit{check\_fix}(\textit{kern}(i))(\text{´Kern´})$;

This code is used in section 132.

85.   The ligature/kerning program comes next. Before we can put it out in VPL format, we need to make a table of "labels" that will be inserted into the program. For each character c whose *tag* is *lig_tag* and whose starting address is r, we will store the pair (c, r) in the *label_table* array. If there's a boundary-char program starting at r, we also store the pair $(256, r)$. This array is sorted by its second components, using the simple method of straight insertion.

⟨ Globals in the outer block 7 ⟩ +≡
label_table: **array** [0 . . 258] **of record**
    cc: 0 . . 256;
    rr: 0 . . *lig_size*;
    end;
label_ptr: 0 . . 257;   { the largest entry in *label_table* }
sort_ptr: 0 . . 257;   { index into *label_table* }
boundary_char: 0 . . 256;   { boundary character, or 256 if none }
bchar_label: 0 . . ´77777;   { beginning of boundary character program }

86.   ⟨ Set initial values 11 ⟩ +≡
  boundary_char ← 256; *bchar_label* ← ´77777;
  label_ptr ← 0; *label_table*[0].*rr* ← 0;   { a sentinel appears at the bottom }

87.   We'll also identify and remove inaccessible program steps, using the *activity* array.

  define *unreachable* = 0   { a program step not known to be reachable }
  define *pass_through* = 1   { a program step passed through on initialization }
  define *accessible* = 2   { a program step that can be relevant }

⟨ Globals in the outer block 7 ⟩ +≡
activity: **array** [0 . . *lig_size*] **of** *unreachable* . . *accessible*;
ai, *acti*: 0 . . *lig_size*;   { indices into *activity* }

88.   ⟨ Do the ligatures and kerns 88 ⟩ ≡
  if *nl* > 0 **then**
    begin for *ai* ← 0 **to** *nl* − 1 **do** *activity*[*ai*] ← *unreachable*;
    ⟨ Check for a boundary char 91 ⟩;

  else begin *left*; *out*(´CHARIC´); *out_fix*(*italic*(*c*)); *right*;
    end

This code is used in section 100.

105. ⟨Output the applicable part of the ligature/kern program as a comment 105⟩ ≡
  begin *left*; *out*(´COMMENT´); *out_ln*;
  i ← *remainder*(*c*); *r* ← *lig_step*(*i*);
  if *tfm*[*r*] > *stop_flag* **then** *i* ← 256 * *tfm*[*r* + 2] + *tfm*[*r* + 3];
  repeat ⟨Output step *i* of the ligature/kern program 96⟩;
    if *tfm*[*k*] ≥ *stop_flag* **then** *i* ← *nl*
    else *i* ← *i* + 1 + *tfm*[*k*];
  until *i* ≥ *nl*;
  right;
  end

This code is used in section 100.

106.   We want to make sure that there is no cycle of characters linked together by *list_tag* entries, since such a cycle would get TEX into an endless loop. If such a cycle exists, the routine here detects it when processing the largest character code in the cycle.

⟨Output the character link unless there is a problem 106⟩ ≡
  begin $r \leftarrow remainder(c)$;
  if $nonexistent(r)$ **then**
    begin $bad\_char(\text{´Character}_{\sqcup}\text{list}_{\sqcup}\text{link}_{\sqcup}\text{to´})(r)$; $reset\_tag(c)$;
    end
  else begin while $(r < c) \wedge (tag(r) = list\_tag)$ **do** $r \leftarrow remainder(r)$;
    if $r = c$ **then**
      begin $bad(\text{´Cycle}_{\sqcup}\text{in}_{\sqcup}\text{a}_{\sqcup}\text{character}_{\sqcup}\text{list!´})$; $print(\text{´Character}_{\sqcup}\text{´})$; $print\_octal(c)$;
      $print\_ln(\text{´}_{\sqcup}\text{now}_{\sqcup}\text{ends}_{\sqcup}\text{the}_{\sqcup}\text{list.´})$; $reset\_tag(c)$;
      end
    else begin $left$; $out(\text{´NEXTLARGER´})$; $out\_char(remainder(c))$; $right$;
      end;
    end;
  end

This code is used in section 100.

107.   ⟨Output an extensible character recipe 107⟩ ≡
  if $remainder(c) \geq ne$ **then**
    begin $range\_error(\text{´Extensible´})$; $reset\_tag(c)$;
    end
  else begin $left$; $out(\text{´VARCHAR´})$; out_ln; ⟨Output the extensible pieces that exist 108⟩;
    $right$;
    end

This code is used in section 100.

108.   ⟨Output the extensible pieces that exist 108⟩ ≡
  for $k \leftarrow 0$ **to** 3 **do**
    if $(k = 3) \vee (tfm[exten(c) + k] > 0)$ **then**
      begin $left$;
      case k **of**
      0: $out(\text{´TOP´})$; 1: $out(\text{´MID´})$; 2: $out(\text{´BOT´})$; 3: $out(\text{´REP´})$
      end;
      if $nonexistent(tfm[exten(c) + k])$ **then** $out\_char(c)$
      else $out\_char(tfm[exten(c) + k])$;
      $right$;
      end

This code is used in section 107.

109.   Some of the extensible recipes may not actually be used, but TeX will complain about them anyway if they refer to nonexistent characters. Therefore VFtoVP must check them too.

⟨ Check the extensible recipes 109 ⟩ ≡
  if $ne > 0$ **then**
    for $c \leftarrow 0$ **to** $ne - 1$ **do**
      for $d \leftarrow 0$ **to** 3 **do**
        begin $k \leftarrow 4 * (\mathit{exten\_base} + c) + d$;
        if $(\mathit{tfm}[k] > 0) \vee (d = 3)$ **then**
          begin if $\mathit{nonexistent}(\mathit{tfm}[k])$ **then**
            begin $\mathit{bad\_char}(\text{´Extensible}_\sqcup\text{recipe}_\sqcup\text{involves}_\sqcup\text{the´})(\mathit{tfm}[k])$;
            if $d < 3$ **then** $\mathit{tfm}[k] \leftarrow 0$;
            end;
          end;
        end

This code is used in section 134.

110.   Checking for ligature loops.   We have programmed almost everything but the most interesting calculation of all, which has been saved for last as a special treat. TEX's extended ligature mechanism allows unwary users to specify sequences of ligature replacements that never terminate. For example, the pair of commands

$$\text{(/LIG } x \; y) \; \text{(/LIG } y \; x)$$

alternately replaces character x by character y and vice versa. A similar loop occurs if (LIG/ z y) occurs in the program for x and (LIG/ z x) occurs in the program for y.

More complicated loops are also possible. For example, suppose the ligature programs for x and y are

$$\text{(LABEL } x)\text{(/LIG/ } z \; w)\text{(/LIG/> } w \; y) \; \ldots,$$
$$\text{(LABEL } y)\text{(LIG } w \; x) \; \ldots;$$

then the adjacent characters xz change to xwz, $xywz$, xxz, $xxwz$, $\ldots$, ad infinitum.

111.   To detect such loops, VFtoVP attempts to evaluate the function $f(x, y)$ for all character pairs x and y, where f is defined as follows: If the current character is x and the next character is y, we say the "cursor" is between x and y; when the cursor first moves past y, the character immediately to its left is $f(x, y)$. This function is defined if and only if no infinite loop is generated when the cursor is between x and y.

The function $f(x, y)$ can be defined recursively. It turns out that all pairs (x, y) belong to one of five classes. The simplest class has $f(x, y) = y$; this happens if there's no ligature between x and y, or in the cases LIG/> and /LIG/>>. Another simple class arises when there's a LIG or /LIG> between x and y, generating the character z; then $f(x, y) = z$. Otherwise we always have $f(x, y)$ equal to either $f(x, z)$ or $f(z, y)$ or $f(f(x, z), y)$, where z is the inserted ligature character.

The first two of these classes can be merged; we can also consider (x, y) to belong to the simple class when $f(x, y)$ has been evaluated. For technical reasons we allow x to be 256 (for the boundary character at the left) or 257 (in cases when an error has been detected).

For each pair (x, y) having a ligature program step, we store (x, y) in a hash table from which the values z and *class* can be read.

define *simple* $= 0$ $\{ f(x, y) = z \}$
define *left_z* $= 1$ $\{ f(x, y) = f(z, y) \}$
define *right_z* $= 2$ $\{ f(x, y) = f(x, z) \}$
define *both_z* $= 3$ $\{ f(x, y) = f(f(x, z), y) \}$
define *pending* $= 4$ $\{ f(x, y) \text{ is being evaluated} \}$

⟨ Globals in the outer block 7 ⟩ +≡
hash: **array** $[0 .. hash\_size]$ **of** $0 .. 66048$; $\{ 256x + y + 1 \text{ for } x \le 257 \text{ and } y \le 255 \}$

    end

This code is used in section 88.

113. ⟨Enter data for character c starting at location i in the hash table 113⟩ ≡

  repeat $hash\_input$; $k \leftarrow tfm[lig\_step(i)]$;

    if $k \geq stop\_flag$ **then** $i \leftarrow nl$

    else $i \leftarrow i + 1 + k$;

  until $i \geq nl$

This code is used in sections 112 and 112.

114.   We use an "ordered hash table" with linear probing, because such a table is efficient when the lookup of a random key tends to be unsuccessful.

procedure *hash_input*;   {enter data for character c and command i}
   label *exit*;
   var *cc*: *simple* .. *both_z*;   {class of data being entered}
      zz: 0 .. 255;   {function value or ligature character being entered}
      y: 0 .. 255;   {the character after the cursor}
      key: *integer*;   {value to be stored in *hash*}
      t: *integer*;   {temporary register for swapping}
   begin if *hash_ptr* = *hash_size* **then return**;
   ⟨Compute the command parameters y, *cc*, and *zz* 115⟩;
   key ← 256 * *c* + *y* + 1; *h* ← (1009 * *key*) **mod** *hash_size*;
   while *hash*[*h*] > 0 **do**
      begin if *hash*[*h*] ≤ *key* **then**
         begin if *hash*[*h*] = *key* **then return**;   {unused ligature command}
         t ← *hash*[*h*]; *hash*[*h*] ← *key*; *key* ← *t*;   {do ordered-hash-table insertion}
         t ← *class*[*h*]; *class*[*h*] ← *cc*; *cc* ← *t*;   {namely, do a swap}
         t ← *lig_z*[*h*]; *lig_z*[*h*] ← *zz*; *zz* ← *t*;
         end;
      if *h* > 0 **then** *decr*(*h*) **else** *h* ← *hash_size*;
      end;
   hash[*h*] ← *key*; *class*[*h*] ← *cc*; *lig_z*[*h*] ← *zz*; *incr*(*hash_ptr*); *hash_list*[*hash_ptr*] ← *h*;
exit: **end**;

115.   We must store kern commands as well as ligature commands, because the former might make the latter inapplicable.

⟨Compute the command parameters y, *cc*, and *zz* 115⟩ ≡
   k ← *lig_step*(*i*); *y* ← *tfm*[*k* + 1]; *t* ← *tfm*[*k* + 2]; *cc* ← *simple*; *zz* ← *tfm*[*k* + 3];
   if *t* ≥ *kern_flag* **then** *zz* ← *y*
   else begin case *t* **of**
      0, 6: *do_nothing*;   {LIG,/LIG>}
      5, 11: *zz* ← *y*;   {LIG/>, /LIG/>>}
      1, 7: *cc* ← *left_z*;   {LIG/, /LIG/>}
      2: *cc* ← *right_z*;   {/LIG}
      3: *cc* ← *both_z*;   {/LIG/}
      end;   {there are no other cases}
      end

This code is used in section 114.

116.   Evaluation of $f(x, y)$ is handled by two mutually recursive procedures. Kind of a neat algorithm, generalizing a depth-first search.

function $f(h, x, y : index)$: *index*; *forward*;   {compute f for arguments known to be in *hash*[*h*]}
function *eval*$(x, y : index)$: *index*;   {compute $f(x, y)$ with hashtable lookup}
   var *key*: *integer*;   {value sought in hash table}
   begin *key* ← 256 * *x* + *y* + 1; *h* ← (1009 * *key*) **mod** *hash_size*;
   while *hash*[*h*] > *key* **do**
      if *h* > 0 **then** *decr*(*h*) **else** *h* ← *hash_size*;
   if *hash*[*h*] < *key* **then** *eval* ← *y*   {not in ordered hash table}
   else *eval* ← *f*(*h*, *x*, *y*);
   end;

117.   Pascal's beastly convention for *forward* declarations prevents us from saying **function** $f(h, x, y :$ *index*): *index* here.

function f;
  begin case *class*[h] **of**
  simple: *do_nothing*;
  left_z: **begin** *class*[h] $\leftarrow$ *pending*; *lig_z*[h] $\leftarrow$ *eval*(*lig_z*[h], y); *class*[h] $\leftarrow$ *simple*;
     end;
  right_z: **begin** *class*[h] $\leftarrow$ *pending*; *lig_z*[h] $\leftarrow$ *eval*(x, *lig_z*[h]); *class*[h] $\leftarrow$ *simple*;
     end;
  both_z: **begin** *class*[h] $\leftarrow$ *pending*; *lig_z*[h] $\leftarrow$ *eval*(*eval*(x, *lig_z*[h]), y); *class*[h] $\leftarrow$ *simple*;
     end;
  pending: **begin** *x_lig_cycle* $\leftarrow$ x; *y_lig_cycle* $\leftarrow$ y; *lig_z*[h] $\leftarrow$ 257; *class*[h] $\leftarrow$ *simple*;
     end;   { the value 257 will break all cycles, since it's not in *hash* }
  end;   { there are no other cases }
  $f \leftarrow$ *lig_z*[h];
  end;

118.   Outputting the VF info.   The routines we've used for output from the *tfm* array have counter-
parts for output from *vf*. One difference is that the string outputs from *vf* need to be checked for balanced
parentheses. The *string_balance* routine tests the string of length *l* that starts at location *k*.

function *string_balance*(*k, l* : *integer*): *boolean*;
  label *not_found*, *exit*;
  var *j, bal*: *integer*;
  begin if *l* > 0 **then**
    if *vf*[*k*] = "␣" **then goto** *not_found*;   { a leading blank is considered unbalanced }
  bal ← 0;
  for *j* ← *k* **to** *k* + *l* − 1 **do**
    begin if (*vf*[*j*] < "␣") ∨ (*vf*[*j*] ≥ 127) **then goto** *not_found*;
    if *vf*[*j*] = "(" **then** *incr*(*bal*)
    else if *vf*[*j*] = ")" **then**
        if *bal* = 0 **then goto** *not_found*
        else *decr*(*bal*);
    end;
  if *bal* > 0 **then goto** *not_found*;
  string_balance ← *true*; **return**;
not_found: *string_balance* ← *false*;
exit: **end**;

119.   **define** *bad_vf*(#) ≡
        begin *perfect* ← *false*;
        if *chars_on_line* > 0 **then** *print_ln*(´␣´);
        chars_on_line ← 0; *print_ln*(´Bad␣VF␣file:␣´, #);
        end

⟨ Do the virtual font title 119 ⟩ ≡
  if *string_balance*(0, *font_start*[0]) **then**
    begin *left*; *out*(´VTITLE␣´);
    for *k* ← 0 **to** *font_start*[0] − 1 **do** *out*(*xchr*[*vf*[*k*]]);
    right;
    end
  else *bad_vf*(´Title␣is␣not␣a␣balanced␣ASCII␣string´)

This code is used in section 132.

120.   We can re-use some code by moving *fix_word* data to *tfm*, using the fact that the design size has
already been output.

procedure *out_as_fix*(*x* : *integer*);
  var *k*: 1 . . 3;
  begin if *abs*(*x*) ≥ ´100000000 **then**
    begin *bad_vf*(´Oversize␣dimension␣has␣been␣reset␣to␣zero.´); *x* ← 0;
    end;
  if *x* ≥ 0 **then** *tfm*[*design_size*] ← 0
  else begin *tfm*[*design_size*] ← 255; *x* ← *x* + ´100000000;
    end;
  for *k* ← 3 **downto** 1 **do**
    begin *tfm*[*design_size* + *k*] ← *x* **mod** 256; *x* ← *x* **div** 256;
    end;
  out_fix(*design_size*);
  end;

121. ⟨Do the local fonts 121⟩ ≡
  for $f \leftarrow 0$ **to** $font\_ptr - 1$ **do**
    begin $left$; $out(\text{`MAPFONT}_\sqcup\text{D}_\sqcup\text{'}, f : 1)$; out_ln; ⟨Output the font area and name 122⟩;

    $right$;
    end

This code is used in section 121.

123. Now we get to the interesting part of VF output, where DVI commands are translated into symbolic form. The VPL language is a subset of DVI, so we sometimes need to output semantic equivalents of the commands instead of producing a literal translation. This causes a small but tolerable loss of efficiency. We need to simulate the stack used by DVI-reading software.

⟨Globals in the outer block 7⟩ +≡
top: $0 .. max\_stack$; {DVI stack pointer}
$wstack, xstack, ystack, zstack$: **array** $[0 .. max\_stack]$ **of** $integer$;
        {stacked values of DVI registers w, x, y, z}
vf_limit: $0 .. vf\_size$; {the current packet ends here}
o: $byte$; {the current opcode}

124. ⟨Do the packet for character c 124⟩ ≡
  if $packet\_start[c] = vf\_size$ **then** bad_vf(´Missing␣packet␣for␣character␣´, c : 1)

131.   The main program.   The routines sketched out so far need to be packaged into separate pro-
cedures, on some systems, since some Pascal compilers place a strict limit on the size of a routine. The
packaging is done here in an attempt to avoid some system-dependent changes.

First come the *vf_input* and *organize* procedures, which read the input data and get ready for subsequent
events. If something goes wrong, the routines return *false*.

function *vf_input*: *boolean*;
  label *final_end*, *exit*;
  var *vf_ptr*: 0 .. *vf_size*;   { an index into *vf* }
    k: *integer*;   { all-purpose index }
    c: *integer*;   { character code }
  begin ⟨ Read the whole VF file 31 ⟩;
  vf_input ← *true*; **return**;
final_end: *vf_input* ← *false*;
exit: **end**;

function *organize*: *boolean*;
  label *final_end*, *exit*;
  var *tfm_ptr*: *index*;   { an index into *tfm* }
  begin ⟨ Read the whole TFM file 24 ⟩;
  ⟨ Set subfile sizes *lh*, *bc*, ..., *np* 25 ⟩;
  ⟨ Compute the base addresses 27 ⟩;
  organize ← *vf_input*; **return**;
final_end: *organize* ← *false*;
exit: **end**;

132.   Next we do the simple things.

procedure *do_simple_things*;
  var *i*: 0 .. ´77777;   { an index to words of a subfile }
    f: 0 .. *vf_size*;   { local font number }
    k: *integer*;   { all-purpose index }
  begin ⟨ Do the virtual font title 119 ⟩;
  ⟨ Do the header 70 ⟩;
  ⟨ Do the parameters 80 ⟩;
  ⟨ Do the local fonts 121 ⟩;
  ⟨ Check the *fix_word* entries 84 ⟩;
  end;

133.   And then there's a routine for individual characters.

function *do_map*(*c* : *byte*): *boolean*;
  label *final_end*, *exit*;
  var *k*: *integer*; *f*: 0 . . *vf_size*;   { current font number }
  begin ⟨ Do the packet for character *c* 124 ⟩;
  do_map ← *true*; **return**;
final_end: *do_map* ← *false*;
exit: **end**;

function *do_characters*: *boolean*;
  label *final_end*, *exit*;
  var *c*: *byte*;   { character being done }
    k: *index*;   { a random index }
    ai: 0 . . *lig_size*;   { index into *activity* }
  begin ⟨ Do the characters 100 ⟩;
  do_characters ← *true*; **return**;
final_end: *do_characters* ← *false*;
exit: **end**;

134.   Here is where VFtoVP begins and ends.

  begin *initialize*;
  if ¬*organize* **then** **goto** *final_end*;
  do_simple_things;
  ⟨ Do the ligatures and kerns 88 ⟩;
  ⟨ Check the extensible recipes 109 ⟩;
  if ¬*do_characters* **then** **goto** *final_end*;
  print_ln(´.´);
  if *level* ≠ 0 **then** *print_ln*(´This␣program␣isn´´t␣working!´);
  if ¬*perfect* **then**
    begin *out*(´(COMMENT␣THE␣TFM␣AND/OR␣VF␣FILE␣WAS␣BAD,␣´);
    out(´SO␣THE␣DATA␣HAS␣BEEN␣CHANGED!)´); *write_ln*(*vpl_file*);
    end;
final_end: **end**.

135.   System-dependent changes.   This section should be replaced, if necessary, by changes to the program that are necessary to make `VFtoVP` work at a particular installation. It is usually best to design your change file so that all changes to previous sections preserve the section numbering; then everybody's version will be consistent with the printed program. More extensive changes, which introduce new sections, can be inserted here; then only the index itself will get a new section number.

136.   Index.   Pointers to error messages appear here together with the section numbers where each identifier is used.

⟨ Read and store a font definition 35 ⟩   Used in section 33.

⟨ Read and store the font definitions and character packets 33 ⟩   Used in section 31.

⟨ Read and verify the postamble 34 ⟩   Used in section 31.

⟨ Read the local font's TFM file and record the characters it contains 39 ⟩   Used in section 35.

⟨ Read the preamble command 32 ⟩   Used in section 31.

⟨ Read the whole TFM file 24 ⟩   Used in section 131.

⟨ Read the whole VF file 31 ⟩   Used in section 131.

⟨ Reduce l by one, preserving the invariants 59 ⟩   Used in section 58.

⟨ Reduce negative to positive 65 ⟩   Used in section 62.

⟨ Set initial values 11, 21, 43, 50, 55, 68, 86 ⟩   Used in section 2.

⟨ Set subfile sizes lh, bc, ..., np 25 ⟩   Used in section 131.

⟨ Set the true $font\_type$ 75 ⟩   Used in section 70.

⟨ Take care of commenting out unreachable steps 95 ⟩   Used in section 93.

⟨ Types in the outer block 5, 22 ⟩   Used in section 2.
