		Section	Page

1.   Introduction.   This is XƎTEX, a program derived from and extending the capabilities of TEX, a document compiler intended to produce typesetting of high quality. The Pascal program that follows is the definition of TEX82, a standard version of TEX that is designed to be highly portable so that identical output will be obtainable on a great variety of computers.

The main purpose of the following program is to explain the algorithms of TEX as clearly as possible. As a result, the program will not necessarily be very efficient when a particular Pascal compiler has translated it into a particular machine language. However, the program has been written so that it can be tuned to run efficiently in a wide variety of operating environments by making comparatively few changes. Such flexibility is possible because the documentation that follows is written in the WEB language, which is at a higher level than Pascal; the preprocessing step that converts WEB to Pascal is able to introduce most of the necessary refinements. Semi-automatic translation to other languages is also feasible, because the program below does not make extensive use of features that are peculiar to Pascal.

A large piece of software like TEX has inherent complexity that cannot be reduced below a certain level of difficulty, although each individual part is fairly simple by itself. The WEB language is intended to make the algorithms as readable as possible, by reflecting the way the individual program pieces fit together and by providing the cross-references that connect different parts. Detailed comments about what is going on, and about why things were done in certain ways, have been liberally sprinkled throughout the program. These comments explain features of the implementation, but they rarely attempt to explain the TEX language itself, since the reader is supposed to be familiar with *The TEXbook*.

2.   The present implementation has a long ancestry, beginning in the summer of 1977, when Michael F. Plass and Frank M. Liang designed and coded a prototype based on some specifications that the author had made in May of that year. This original protoTEX included macro definitions and elementary manipulations on boxes and glue, but it did not have line-breaking, page-breaking, mathematical formulas, alignment routines, error recovery, or the present semantic nest; furthermore, it used character lists instead of token lists, so that a control sequence like \halign was represented by a list of seven characters. A complete version of TEX was designed and coded by the author in late 1977 and early 1978; that program, like its prototype, was written in the SAIL language, for which an excellent debugging system was available. Preliminary plans to convert the SAIL code into a form somewhat like the present "web" were developed by Luis Trabb Pardo and the author at the beginning of 1979, and a complete implementation was created by Ignacio A. Zabala in 1979 and 1980. The TEX82 program, which was written by the author during the latter part of 1981 and the early part of 1982, also incorporates ideas from the 1979 implementation of TEX in MESA that was written by Leonidas Guibas, Robert Sedgewick, and Douglas Wyatt at the Xerox Palo Alto Research Center. Several hundred refinements were introduced into TEX82 based on the experiences gained with the original implementations, so that essentially every part of the system has been substantially improved. After the appearance of "Version 0" in September 1982, this program benefited greatly from the comments of many other people, notably David R. Fuchs and Howard W. Trickey. A final revision in September 1989 extended the input character set to eight-bit codes and introduced the ability to hyphenate words from different languages, based on some ideas of Michael J. Ferguson.

No doubt there still is plenty of room for improvement, but the author is firmly committed to keeping TEX82 "frozen" from now on; stability and reliability are to be its main virtues.

On the other hand, the WEB description can be extended without changing the core of TEX82 itself, and the program has been designed so that such extensions are not extremely difficult to make. The *banner* string defined here should be changed whenever TEX undergoes any modifications, so that it will be clear which version of TEX might be the guilty party when a problem arises.

This program contains code for various features extending TEX, therefore this program is called 'X͟ǝTEX' and not 'TEX'; the official name 'TEX' by itself is reserved for software systems that are fully compatible with each other. A special test suite called the "TRIP test" is available for helping to determine whether a particular implementation deserves to be known as 'TEX' [cf. Stanford Computer Science report CS1027, November 1984].

A similar test suite called the "e-TRIP test" is available for helping to determine whether a particular implementation deserves to be known as 'ε-TEX'.

define $eTeX\_version = 2$ { \eTeXversion }
define $eTeX\_revision \equiv$ ".6"   { \eTeXrevision }
define $eTeX\_version\_string \equiv$ ´-2.6´   { current ε-TEX version }

define $XeTeX\_version = 0$ { \XeTeXversion }
define $XeTeX\_revision \equiv$ ".999996"   { \XeTeXrevision }
define $XeTeX\_version\_string \equiv$ ´-0.999996´   { current X͟ǝTEX version }

define $XeTeX\_banner \equiv$ ´This␣is␣XeTeX,␣Version␣3.141592653´, $eTeX\_version\_string$,
        $XeTeX\_version\_string$ { printed when X͟ǝTEX starts }

define $banner \equiv$ ´This␣is␣TeX,␣Version␣3.141592653´   { printed when TEX starts }

define $TEX \equiv XETEX$ { change program name into $XETEX$ }

define $TeXXeT\_code = 0$ { the TEX--X͟ǝT feature is optional }

define $XeTeX\_dash\_break\_code = 1$ { non-zero to enable breaks after en- and em-dashes }

define $XeTeX\_upwards\_code = 2$ { non-zero if the main vertical list is being built upwards }
define $XeTeX\_use\_glyph\_metrics\_code = 3$ { non-zero to use exact glyph height/depth }
define $XeTeX\_inter\_char\_tokens\_code = 4$ { non-zero to enable \XeTeXinterchartokens insertion }

define $XeTeX\_input\_normalization\_code = 5$ { normalization mode:, 1 for NFC, 2 for NFD, else none }

define $XeTeX\_input\_mode\_icu\_mapping = 5$
define $XeTeX\_default\_input\_encoding\_code = 7$ { str_number of encoding name if $mode = \text{ICU}$ }
define $XeTeX\_tracing\_fonts\_code = 8$ { non-zero to log native fonts used }
define $XeTeX\_interword\_space\_shaping\_code = 9$ { controls shaping of space chars in context when
          using native fonts; set to 1 for contextual adjustment of space width only, and 2 for full
          cross-space shaping (e.g. multi-word ligatures) }
define $XeTeX\_generate\_actual\_text\_code = 10$ { controls output of /ActualText for native-word nodes }
define $XeTeX\_hyphenatable\_length\_code = 11$ { sets maximum hyphenatable word length }
define $eTeX\_states = 12$ { number of ε-TₑX state variables in $eqtb$ }

3.   Different Pascals have slightly different conventions, and the present program expresses TₑX in terms of the Pascal that was available to the author in 1982. Constructions that apply to this particular compiler, which we shall call Pascal-H, should help the reader see how to make an appropriate interface for other systems if necessary. (Pascal-H is Charles Hedrick's modification of a compiler for the DECsystem-10 that was originally developed at the University of Hamburg; cf. *Software—Practice and Experience* **6** (1976), 29–42. The TₑX program below is intended to be adaptable, without extensive changes, to most other versions of Pascal, so it does not fully use the admirable features of Pascal-H. Indeed, a conscious effort has been made here to avoid using several idiosyncratic features of standard Pascal itself, so that most of the code can be translated mechanically into other high-level languages. For example, the '**with**' and '*new*' features are not used, nor are pointer types, set types, or enumerated scalar types; there are no '**var**' parameters, except in the case of files — ε-TₑX, however, does use '**var**' parameters for the *reverse* function; there are no tag fields on variant records; there are no assignments $real \leftarrow integer$; no procedures are declared local to other procedures.)

The portions of this program that involve system-dependent code, where changes might be necessary because of differences between Pascal compilers and/or differences between operating systems, can be identified by looking at the sections whose numbers are listed under 'system dependencies' in the index. Furthermore, the index entries for 'dirty Pascal' list all places where the restrictions of Pascal have not been followed perfectly, for one reason or another.

Incidentally, Pascal's standard *round* function can be problematical, because it disagrees with the IEEE floating-point standard. Many implementors have therefore chosen to substitute their own home-grown rounding procedure.

4.   The program begins with a normal Pascal program heading, whose components will be filled in later, using the conventions of WEB. For example, the portion of the program called '⟨Global variables 13⟩' below will be replaced by a sequence of variable declarations that starts in §13 of this documentation. In this way, we are able to define each individual global variable when we are prepared to understand what it means; we do not have to define all of the globals at once. Cross references in §13, where it says "See also sections 20, 26, . . . ," also make it possible to look at the set of all global variables, if desired. Similar remarks apply to the other portions of the program heading.

Actually the heading shown here is not quite normal: The **program** line does not mention any *output* file, because Pascal-H would ask the TEX user to specify a file name if *output* were specified here.

> **define** *mtype* ≡ *t*@&*y*@&*p*@&*e*   { this is a WEB coding trick: }
> **format** *mtype* ≡ *type*   { '**mtype**' will be equivalent to '**type**' }
> **format** *type* ≡ *true*   { but '*type*' will not be treated as a reserved word }

⟨Compiler directives 9⟩
program *TEX* ;   { all file names are defined dynamically }
  label ⟨Labels in the outer block 6⟩
  const ⟨Constants in the outer block 11⟩
  mtype ⟨Types in the outer block 18⟩
  var ⟨Global variables 13⟩

  procedure *initialize*;   { this procedure gets things started properly }
    var ⟨Local variables for initialization 19⟩
    begin ⟨Initialize whatever TEX might access 8⟩
    end;
  ⟨Basic printing procedures 57⟩
  ⟨Error handling procedures 82⟩

5.   The overall TEX program begins with the heading just shown, after which comes a bunch of procedure declarations and function declarations. Finally we will get to the main program, which begins with the comment '*start_here*'. If you want to skip down to the main program now, you can look up '*start_here*' in the index. But the author suggests that the best way to understand this program is to follow pretty much the order of TEX's components as they appear in the WEB description you are now reading, since the present ordering is intended to combine the advantages of the "bottom up" and "top down" approaches to the problem of understanding a somewhat complicated system.

6.   Three labels must be declared in the main program, so we give them symbolic names.

> **define** *start_of_TEX* = 1   { go here when TEX's variables are initialized }
> **define** *end_of_TEX* = 9998   { go here to close files and terminate gracefully }
> **define** *final_end* = 9999   { this label marks the ending of the program }

⟨Labels in the outer block 6⟩ ≡
  start_of_TEX, *end_of_TEX*, *final_end*;   { key control points }
This code is used in section 4.

7.   Some of the code below is intended to be used only when diagnosing the strange behavior that sometimes occurs when TEX is being installed or when system wizards are fooling around with TEX without quite knowing what they are doing. Such code will not normally be compiled; it is delimited by the codewords '**debug** . . . **gubed**', with apologies to people who wish to preserve the purity of English.

Similarly, there is some conditional code delimited by '**stat** . . . **tats**' that is intended for use when statistics are to be kept about TEX's memory usage. The **stat** . . . **tats** code also implements diagnostic information for \tracingparagraphs, \tracingpages, and \tracingrestores.

> **define** *debug* ≡ @{   { change this to '*debug* ≡ ' when debugging }
> **define** *gubed* ≡ @}   { change this to '*gubed* ≡ ' when debugging }
> **format** *debug* ≡ *begin*
> **format** *gubed* ≡ *end*
> **define** *stat* ≡ @{   { change this to '*stat* ≡ ' when gathering usage statistics }
> **define** *tats* ≡ @}   { change this to '*tats* ≡ ' when gathering usage statistics }
> **format** *stat* ≡ *begin*
> **format** *tats* ≡ *end*

8.   This program has two important variations: (1) There is a long and slow version called INITEX, which does the extra calculations needed to initialize TEX's internal tables; and (2) there is a shorter and faster production version, which cuts the initialization to a bare minimum. Parts of the program that are needed in (1) but not in (2) are delimited by the codewords '**init** . . . **tini**'.

> **define** *init* ≡   { change this to '*init* ≡ @{' in the production version }
> **define** *tini* ≡   { change this to '*tini* ≡ @}' in the production version }
> **format** *init* ≡ *begin*
> **format** *tini* ≡ *end*

⟨ Initialize whatever TEX might access 8 ⟩ ≡
  ⟨ Set initial values of key variables 23 ⟩
  init ⟨ Initialize table entries (done by INITEX only) 189 ⟩ **tini**

This code is used in section 4.

9.   If the first character of a Pascal comment is a dollar sign, Pascal-H treats the comment as a list of "compiler directives" that will affect the translation of this program into machine language. The directives shown below specify full checking and inclusion of the Pascal debugger when TEX is being debugged, but they cause range checking and other redundant code to be eliminated when the production system is being generated. Arithmetic overflow will be detected in all cases.

⟨ Compiler directives 9 ⟩ ≡
  @{@&$C−, A+, D−@}   { no range check, catch arithmetic overflow, no debug overhead }
  debug @{@&$C+, D+@} **gubed**   { but turn everything on when debugging }

This code is used in section 4.

10.   This TEX implementation conforms to the rules of the *Pascal User Manual* published by Jensen and
Wirth in 1975, except where system-dependent code is necessary to make a useful system program, and
except in another respect where such conformity would unnecessarily obscure the meaning and clutter up
the code: We assume that **case** statements may include a default case that applies if no matching label is
found. Thus, we shall use constructions like

$$\begin{aligned}
&\textbf{case } x \textbf{ of}\\
&1\colon \langle\,\text{code for } x = 1\,\rangle;\\
&3\colon \langle\,\text{code for } x = 3\,\rangle;\\
&\textbf{othercases } \langle\,\text{code for } x \neq 1 \text{ and } x \neq 3\,\rangle\\
&\textbf{endcases}
\end{aligned}$$

since most Pascal compilers have plugged this hole in the language by incorporating some sort of default
mechanism. For example, the Pascal-H compiler allows '*others*:' as a default label, and other Pascals
allow syntaxes like '**else**' or '**otherwise**' or '*otherwise*:', etc. The definitions of **othercases** and **endcases**
should be changed to agree with local conventions. Note that no semicolon appears before **endcases** in this
program, so the definition of **endcases** should include a semicolon if the compiler wants one. (Of course,
if no default mechanism is available, the **case** statements of TEX will have to be laboriously extended by
listing all remaining cases. People who are stuck with such Pascals have, in fact, done this, successfully but
not happily!)

> **define** *othercases* ≡ *others*:   { default for cases not listed explicitly }
> **define** *endcases* ≡ **end**   { follows the default case in an extended **case** statement }
> **format** *othercases* ≡ *else*
> **format** *endcases* ≡ *end*

11.   The following parameters can be changed at compile time to extend or reduce TeX's capacity. They may have different values in INITEX and in production versions of TeX.

⟨ Constants in the outer block 11 ⟩ ≡

  $mem\_max = 30000$;
      { greatest index in TeX's internal *mem* array; must be strictly less than *max_halfword*; must be equal to *mem_top* in INITEX, otherwise ≥ *mem_top* }

  $mem\_min = 0$;   { smallest index in TeX's internal *mem* array; must be *min_halfword* or more; must be equal to *mem_bot* in INITEX, otherwise ≤ *mem_bot* }

  $buf\_size = 500$;   { maximum number of characters simultaneously present in current lines of open files and in control sequences between \csname and \endcsname; must not exceed *max_halfword* }

  $error\_line = 72$;   { width of context lines on terminal error messages }

  $half\_error\_line = 42$;   { width of first lines of contexts in terminal error messages; should be between 30 and *error_line* − 15 }

  $max\_print\_line = 79$;   { width of longest text lines output; should be at least 60 }

  $stack\_size = 200$;   { maximum number of simultaneous input sources }

  $max\_in\_open = 6$;
      { maximum number of input files and error insertions that can be going on simultaneously }

  $font\_max = 75$;   { maximum internal font number; must not exceed *max_quarterword* and must be at most *font_base* + 256 }

  $font\_mem\_size = 20000$;   { number of words of *font_info* for all fonts }

  $param\_size = 60$;   { maximum number of simultaneous macro parameters }

  $nest\_size = 40$;   { maximum number of semantic levels simultaneously active }

  $max\_strings = 3000$;   { maximum number of strings; must not exceed *max_halfword* }

  $string\_vacancies = 8000$;   { the minimum number of characters that should be available for the user's control sequences and font names, after TeX's own error messages are stored }

  $pool\_size = 32000$;   { maximum number of characters in strings, including all error messages and help texts, and the names of all fonts and control sequences; must exceed *string_vacancies* by the total length of TeX's own strings, which is currently about 23000 }

  $save\_size = 600$;   { space for saving values outside of current group; must be at most *max_halfword* }

  $trie\_size = 8000$;   { space for hyphenation patterns; should be larger for INITEX than it is in production versions of TeX }

  $trie\_op\_size = 500$;   { space for "opcodes" in the hyphenation patterns }

  $dvi\_buf\_size = 800$;   { size of the output buffer; must be a multiple of 8 }

  $file\_name\_size = 40$;   { file names shouldn't be longer than this }

  $pool_name = $ ´TeXformats:TEX.POOL␣␣␣␣␣␣␣␣␣␣␣␣␣␣␣␣␣␣␣␣␣␣´;
      { string of length *file_name_size*; tells where the string pool appears }

This code is used in section 4.

12.   Like the preceding parameters, the following quantities can be changed at compile time to extend or reduce T$_E$X's capacity. But if they are changed, it is necessary to rerun the initialization program INITEX to generate new tables for the production T$_E$X program. One can't simply make helter-skelter changes to the following constants, since certain rather complex initialization numbers are computed from them. They are defined here using WEB macros, instead of being put into Pascal's **const** list, in order to emphasize this distinction.

define $mem\_bot = 0$

{smallest index in the mem array dumped by INITEX; must not be less than mem_min }

define $mem\_top \equiv 30000$ {largest index in the mem array dumped by INITEX; must be substantially larger than mem_bot and not greater than mem_max }

define $font\_base = 0$ {smallest internal font number; must not be less than $min\_quarterword$ }

define $hash\_size = 2100$ {maximum number of control sequences; it should be at most about $(mem\_max - mem\_min)/10$ }

define $hash\_prime = 1777$ {a prime number equal to about 85% of $hash\_size$ }

define $hyph\_size = 307$ {another prime; the number of \hyphenation exceptions }

define $biggest\_char = 65535$ {the largest allowed character number; must be $\leq max\_quarterword$, this refers to UTF16 codepoints that we store in strings, etc; actual character codes can exceed this range, up to $biggest\_usv$ }

define $too\_big\_char = 65536$ {$biggest\_char + 1$ }

define $biggest\_usv = {''}10FFFF$ {the largest Unicode Scalar Value }

define $too\_big\_usv = {''}110000$ {$biggest\_usv + 1$ }

define $number\_usvs = {''}110000$ {$biggest\_usv + 1$ }

define $special\_char = {''}110001$ {$biggest\_usv + 2$ }

define $biggest\_reg = 255$ {the largest allowed register number; must be $\leq max\_quarterword$ }

define $number\_regs = 256$ {$biggest\_reg + 1$ }

define $font\_biggest = 255$ {the real biggest font }

define $number\_fonts = font\_biggest - font\_base + 2$

define $number\_math\_families = 256$

define $number\_math\_fonts = number\_math\_families + number\_math\_families + number\_math\_families$

define $math\_font\_biggest = number\_math\_fonts - 1$

define $text\_size = 0$ {size code for the largest size in a family }

define $script\_size = number\_math\_families$ {size code for the medium size in a family }

define $script\_script\_size = number\_math\_families + number\_math\_families$

{size code for the smallest size in a family }

define $biggest\_lang = 255$ {the largest hyphenation language }

define $too\_big\_lang = 256$ {$biggest\_lang + 1$ }

define $hyphenatable\_length\_limit = 4095$

{hard limit for hyphenatable length; runtime value is $max\_hyphenatable\_length$ }

13.   In case somebody has inadvertently made bad settings of the "constants," T$_E$X checks them using a global variable called bad.

This is the first of many sections of T$_E$X where global variables are defined.

⟨ Global variables 13 ⟩ ≡
bad: $integer$;   {is some "constant" wrong? }

See also sections 20, 26, 30, 32, 39, 50, 54, 61, 77, 80, 83, 100, 108, 114, 121, 137, 138, 139, 140, 146, 181, 190, 199, 207, 239, 272, 279, 282, 283, 301, 316, 327, 331, 334, 335, 338, 339, 340, 363, 391, 397, 416, 421, 422, 444, 472, 481, 515, 524, 528, 547, 548, 555, 562, 567, 574, 584, 585, 590, 628, 631, 641, 652, 682, 685, 686, 695, 703, 726, 762, 767, 812, 818, 862, 869, 871, 873, 876, 881, 887, 895, 920, 940, 953, 959, 961, 975, 980, 997, 1001, 1004, 1025, 1034, 1036, 1043, 1086, 1128, 1320, 1335, 1353, 1359, 1385, 1396, 1400, 1429, 1449, 1462, 1470, 1515, 1561, 1584, 1625, 1627, 1646, 1653, 1669, and 1670.

This code is used in section 4.

14.   Later on we will say 'if $mem\_max \geq max\_halfword$ then $bad \leftarrow 14$', or something similar. (We can't do that until $max\_halfword$ has been defined.)

⟨ Check the "constant" values for consistency 14 ⟩ ≡
   $bad \leftarrow 0;$
   if $(half\_error\_line < 30) \vee (half\_error\_line > error\_line - 15)$ then $bad \leftarrow 1;$
   if $max\_print\_line < 60$ then $bad \leftarrow 2;$
   if dvi_buf_size **mod** $8 \neq 0$ then $bad \leftarrow 3;$
   if $mem\_bot + 1100 > mem\_top$ then $bad \leftarrow 4;$
   if $hash\_prime > hash\_size$ then $bad \leftarrow 5;$
   if $max\_in\_open \geq 128$ then $bad \leftarrow 6;$
   if $mem\_top < 256 + 11$ then $bad \leftarrow 7;$ { we will want $null\_list > 255$ }

See also sections 133, 320, 557, and 1303.

This code is used in section 1386.

15.   Labels are given symbolic names by the following definitions, so that occasional **goto** statements will be meaningful. We insert the label '*exit*' just before the '**end**' of a procedure in which we have used the '**return**' statement defined below; the label '*restart*' is occasionally used at the very beginning of a procedure; and the label '*reswitch*' is occasionally used just prior to a **case** statement in which some cases change the conditions and we wish to branch to the newly applicable case. Loops that are set up with the **loop** construction defined below are commonly exited by going to '*done*' or to '*found*' or to '*not_found*', and they are sometimes repeated by going to '*continue*'. If two or more parts of a subroutine start differently but end up the same, the shared code may be gathered together at '*common_ending*'.

   Incidentally, this program never declares a label that isn't actually used, because some fussy Pascal compilers will complain about redundant labels.

   define $exit = 10$ { go here to leave a procedure }
   define $restart = 20$ { go here to start a procedure again }
   define $reswitch = 21$ { go here to start a case statement again }
   define $continue = 22$ { go here to resume a loop }
   define $done = 30$ { go here to exit a loop }
   define $done1 = 31$ { like $done$, when there is more than one loop }
   define $done2 = 32$ { for exiting the second loop in a long block }
   define $done3 = 33$ { for exiting the third loop in a very long block }
   define $done4 = 34$ { for exiting the fourth loop in an extremely long block }
   define $done5 = 35$ { for exiting the fifth loop in an immense block }
   define $done6 = 36$ { for exiting the sixth loop in a block }
   define $found = 40$ { go here when you've found it }
   define $found1 = 41$ { like $found$, when there's more than one per routine }
   define $found2 = 42$ { like $found$, when there's more than two per routine }
   define $not\_found = 45$ { go here when you've found nothing }
   define $not\_found1 = 46$ { like not_found, when there's more than one }
   define $not\_found2 = 47$ { like not_found, when there's more than two }
   define $not\_found3 = 48$ { like not_found, when there's more than three }
   define $not\_found4 = 49$ { like not_found, when there's more than four }
   define $common\_ending = 50$ { go here when you want to merge with another branch }

16.   Here are some macros for common programming idioms.

> **define** $incr(\#) \equiv \# \leftarrow \# + 1$ { increase a variable by unity }
> **define** $decr(\#) \equiv \# \leftarrow \# - 1$ { decrease a variable by unity }
> **define** $negate(\#) \equiv \# \leftarrow -\#$ { change the sign of a variable }
> **define** $loop \equiv$ **while** $true$ **do**   { repeat over and over until a **goto** happens }
> **format** $loop \equiv xclause$ { WEB's **xclause** acts like '**while** $true$ **do**' }
> **define** $do\_nothing \equiv$ { empty statement }
> **define** $return \equiv$ **goto** $exit$ { terminate a procedure call }
> **format** $return \equiv nil$
> **define** $empty = 0$ { symbolic name for a null constant }

17.   The character set.   In order to make T_EX readily portable to a wide variety of computers, all of its input text is converted to an internal eight-bit code that includes standard ASCII, the "American Standard Code for Information Interchange." This conversion is done immediately when each character is read in. Conversely, characters are converted from ASCII to the user's external representation just before they are output to a text file.

Such an internal code is relevant to users of T_EX primarily because it governs the positions of characters in the fonts. For example, the character 'A' has ASCII code $65 = \;´101$, and when T_EX typesets this letter it specifies character number 65 in the current font. If that font actually has 'A' in a different position, T_EX doesn't know what the real position is; the program that does the actual printing from T_EX's device-independent files is responsible for converting from ASCII to a particular font encoding.

T_EX's internal code also defines the value of constants that begin with a reverse apostrophe; and it provides an index to the \catcode, \mathcode, \uccode, \lccode, and \delcode tables.

18.   Characters of text that have been converted to T_EX's internal form are said to be of type *ASCII_code*, which is a subrange of the integers. For xetex, we rename *ASCII_code* as *UTF16_code*. But we also have a new type *UTF8_code*, used when we construct filenames to pass to the system libraries.

> **define** *ASCII_code* ≡ *UTF16_code*
> **define** *packed_ASCII_code* ≡ *packed_UTF16_code*

⟨ Types in the outer block 18 ⟩ ≡
  ASCII_code = 0 .. *biggest_char*;   { 16-bit numbers }
  UTF8_code = 0 .. 255;   { 8-bit numbers }
  UnicodeScalar = 0 .. *biggest_usv*;   { Unicode scalars }

This code is used in section 4.

19.   The original Pascal compiler was designed in the late 60s, when six-bit character sets were common, so it did not make provision for lowercase letters. Nowadays, of course, we need to deal with both capital and small letters in a convenient way, especially in a program for typesetting; so the present specification of T_EX has been written under the assumption that the Pascal compiler and run-time system permit the use of text files with more than 64 distinguishable characters. More precisely, we assume that the character set contains at least the letters and symbols associated with ASCII codes $´40$ through $´176$; all of these characters are now available on most computer terminals.

Since we are dealing with more characters than were present in the first Pascal compilers, we have to decide what to call the associated data type. Some Pascals use the original name *char* for the characters in text files, even though there now are more than 64 such characters, while other Pascals consider *char* to be a 64-element subrange of a larger data type that has some other name.

In order to accommodate this difference, we shall use the name *text_char* to stand for the data type of the characters that are converted to and from *ASCII_code* when they are input and output. We shall also assume that *text_char* consists of the elements *chr*(*first_text_char*) through *chr*(*last_text_char*), inclusive. The following definitions should be adjusted if necessary.

> **define** *text_char* ≡ *char*   { the data type of characters in text files }
> **define** *first_text_char* = 0   { ordinal number of the smallest element of *text_char* }
> **define** *last_text_char* = *biggest_char*   { ordinal number of the largest element of *text_char* }

⟨ Local variables for initialization 19 ⟩ ≡
i: *integer*;

See also sections 188 and 981.

This code is used in section 4.

20.   The TEX processor converts between ASCII code and the user's external character set by means of arrays *xord* and *xchr* that are analogous to Pascal's *ord* and *chr* functions.

⟨ Global variables 13 ⟩ +≡
xchr : **array** [*ASCII_code*] **of** *text_char* ;   { specifies conversion of output characters }

21.   Since we are assuming that our Pascal system is able to read and write the visible characters of standard ASCII (although not necessarily using the ASCII codes to represent them), the following assignment statements initialize the standard part of the *xchr* array properly, without needing any system-dependent changes. On the other hand, it is possible to implement TEX with less complete character sets, and in such cases it will be necessary to change something here.

22.   Some of the ASCII codes without visible characters have been given symbolic names in this program because they are used with a special meaning.

> **define** *null_code* = ´0   { ASCII code that might disappear }
> **define** *carriage_return* = ´15   { ASCII code used at end of line }
> **define** *invalid_code* = ´177   { ASCII code that many systems prohibit in text files }

23.   The ASCII code is "standard" only to a certain extent, since many computer installations have found it advantageous to have ready access to more than 94 printing characters. Appendix C of *The TEXbook* gives a complete specification of the intended correspondence between characters and TEX's internal representation.

If TEX is being used on a garden-variety Pascal for which only standard ASCII codes will appear in the input and output files, it doesn't really matter what codes are specified in *xchr* [0 .. ´37], but the safest policy is to blank everything out by using the code shown below.

However, other settings of *xchr* will make TEX more friendly on computers that have an extended character set, so that users can type things like '≠' instead of '\ne'. People with extended character sets can assign codes arbitrarily, giving an *xchr* equivalent to whatever characters the users of TEX are allowed to have in their input files. It is best to make the codes correspond to the intended interpretations as shown in Appendix C whenever possible; but this is not necessary. For example, in countries with an alphabet of more than 26 letters, it is usually best to map the additional letters into codes less than ´40. To get the most "permissive" character set, change ´␣´ on the right of these assignment statements to *chr* (*i*).

⟨ Set initial values of key variables 23 ⟩ ≡
> **for** *i* ← 0 **to** ´37 **do** *xchr* [*i*] ← ´␣´;
> **for** *i* ← ´177 **to** ´377 **do** *xchr* [*i*] ← ´␣´;

See also sections 24, 62, 78, 81, 84, 101, 122, 191, 241, 280, 284, 302, 317, 398, 417, 473, 516, 525, 556, 586, 591, 629, 632, 642, 687, 696, 704, 727, 819, 941, 982, 1044, 1087, 1321, 1336, 1354, 1397, 1412, 1516, 1562, 1628, 1647, and 1671.

This code is used in section 8.

24.   The following system-independent code makes the *xord* array contain a suitable inverse to the information in *xchr* . Note that if *xchr* [*i*] = *xchr* [*j*] where *i* < *j* < ´177, the value of *xord* [*xchr* [*i*]] will turn out to be *j* or more; hence, standard ASCII code numbers will be used instead of codes below ´40 in case there is a coincidence.

⟨ Set initial values of key variables 23 ⟩ +≡
> **for** *i* ← 0 **to** ´176 **do** *xord* [*xchr* [*i*]] ← *i*;

25. Input and output.   The bane of portability is the fact that different operating systems treat input and output quite differently, perhaps because computer scientists have not given sufficient attention to this problem. People have felt somehow that input and output are not part of "real" programming. Well, it is true that some kinds of programming are more fun than others. With existing input/output conventions being so diverse and so messy, the only sources of joy in such parts of the code are the rare occasions when one can find a way to make the program a little less bad than it might have been. We have two choices, either to attack I/O now and get it over with, or to postpone I/O until near the end. Neither prospect is very attractive, so let's get it over with.

The basic operations we need to do are (1) inputting and outputting of text, to or from a file or the user's terminal; (2) inputting and outputting of eight-bit bytes, to or from a file; (3) instructing the operating system to initiate ("open") or to terminate ("close") input or output from a specified file; (4) testing whether the end of an input file has been reached.

TEX needs to deal with two kinds of files. We shall use the term *alpha_file* for a file that contains textual data, and the term *byte_file* for a file that contains eight-bit binary information. These two types turn out to be the same on many computers, but sometimes there is a significant distinction, so we shall be careful to distinguish between them. Standard protocols for transferring such files from computer to computer, via high-speed networks, are now becoming available to more and more communities of users.

The program actually makes use also of a third kind of file, called a *word_file*, when dumping and reloading base information for its own initialization. We shall define a word file later; but it will be possible for us to specify simple operations on word files before they are defined.

⟨ Types in the outer block 18 ⟩ +≡
  eight_bits = 0 . . 255;   { unsigned one-byte quantity }
  alpha_file = **packed file of** *text_char*;   { files that contain textual data }
  byte_file = **packed file of** *eight_bits*;   { files that contain binary data }

26.   Most of what we need to do with respect to input and output can be handled by the I/O facilities that are standard in Pascal, i.e., the routines called *get*, *put*, *eof*, and so on. But standard Pascal does not allow file variables to be associated with file names that are determined at run time, so it cannot be used to implement TEX; some sort of extension to Pascal's ordinary *reset* and *rewrite* is crucial for our purposes. We shall assume that *name_of_file* is a variable of an appropriate type such that the Pascal run-time system being used to implement TEX can open a file whose external name is specified by *name_of_file*.

⟨ Global variables 13 ⟩ +≡
name_of_file: **packed array** [1 . . *file_name_size*] **of** *char*;
    { on some systems this may be a **record** variable }
name_of_file16: **array** [1 . . *file_name_size*] **of** *UTF16_code*;
    { but sometimes we need a UTF16 version of the name }
name_length: 0 . . *file_name_size*;
    { this many characters are actually relevant in *name_of_file* (the rest are blank) }
name_length16: 0 . . *file_name_size*;

27.   The Pascal-H compiler with which the present version of TEX was prepared has extended the rules of Pascal in a very convenient way. To open file f, we can write

$$reset(f, name, \texttt{'/0'}) \qquad \text{for input;}$$
$$rewrite(f, name, \texttt{'/0'}) \qquad \text{for output.}$$

The '*name*' parameter, which is of type '**packed array** $[\langle any \rangle]$ **of** *char*', stands for the name of the external file that is being opened for input or output. Blank spaces that might appear in *name* are ignored.

   The '/0' parameter tells the operating system not to issue its own error messages if something goes wrong. If a file of the specified name cannot be found, or if such a file cannot be opened for some other reason (e.g., someone may already be trying to write the same file), we will have $erstat(f) \neq 0$ after an unsuccessful *reset* or *rewrite*. This allows TEX to undertake appropriate corrective action.

   TEX's file-opening procedures return *false* if no file identified by *name_of_file* could be opened.

define $reset\_OK(\texttt{\#}) \equiv erstat(\texttt{\#}) = 0$
define $rewrite\_OK(\texttt{\#}) \equiv erstat(\texttt{\#}) = 0$

function *a_open_in*(**var** f : *alpha_file*): *boolean*;   { open a text file for input }
  begin $reset(f, name\_of\_file, \texttt{'/0'})$; $a\_open\_in \leftarrow reset\_OK(f)$;
  end;

function *a_open_out*(**var** f : *alpha_file*): *boolean*;   { open a text file for output }
  begin $rewrite(f, name\_of\_file, \texttt{'/0'})$; $a\_open\_out \leftarrow rewrite\_OK(f)$;
  end;

function *b_open_in*(**var** f : *byte_file*): *boolean*;   { open a binary file for input }
  begin $reset(f, name\_of\_file, \texttt{'/0'})$; $b\_open\_in \leftarrow reset\_OK(f)$;
  end;

function *b_open_out*(**var** f : *byte_file*): *boolean*;   { open a binary file for output }
  begin $rewrite(f, name\_of\_file, \texttt{'/0'})$; $b\_open\_out \leftarrow rewrite\_OK(f)$;
  end;

function *w_open_in*(**var** f : *word_file*): *boolean*;   { open a word file for input }
  begin $reset(f, name\_of\_file, \texttt{'/0'})$; $w\_open\_in \leftarrow reset\_OK(f)$;
  end;

function *w_open_out*(**var** f : *word_file*): *boolean*;   { open a word file for output }
  begin $rewrite(f, name\_of\_file, \texttt{'/0'})$; $w\_open\_out \leftarrow rewrite\_OK(f)$;
  end;

28.   Files can be closed with the Pascal-H routine '*close*(f)', which should be used when all input or output with respect to f has been completed. This makes f available to be opened again, if desired; and if f was used for output, the *close* operation makes the corresponding external file appear on the user's area, ready to be read.

   These procedures should not generate error messages if a file is being closed before it has been successfully opened.

procedure *a_close*(**var** f : *alpha_file*);   { close a text file }
  begin $close(f)$;
  end;

procedure *b_close*(**var** f : *byte_file*);   { close a binary file }
  begin $close(f)$;
  end;

procedure *w_close*(**var** f : *word_file*);   { close a word file }
  begin $close(f)$;
  end;

29. Binary input and output are done with Pascal's ordinary *get* and *put* procedures, so we don't have to make any other special arrangements for binary I/O. Text output is also easy to do with standard Pascal routines. The treatment of text input is more difficult, however, because of the necessary translation to *ASCII_code* values. TEX's conventions should be efficient, and they should blend nicely with the user's operating environment.

30. Input from text files is read one line at a time, using a routine called *input_ln*. This function is defined in terms of global variables called *buffer*, *first*, and *last* that will be described in detail later; for now, it suffices for us to know that *buffer* is an array of *ASCII_code* values, and that *first* and *last* are indices into this array representing the beginning and ending of a line of text.

⟨ Global variables 13 ⟩ +≡
buffer: **array** [0 .. *buf_size*] **of** *ASCII_code*;   { lines of characters being read }
first: 0 .. *buf_size*;   { the first unused position in *buffer* }
last: 0 .. *buf_size*;   { end of the line just input to *buffer* }
max_buf_stack: 0 .. *buf_size*;   { largest index used in *buffer* }

31. The *input_ln* function brings the next line of input from the specified file into available positions of the buffer array and returns the value *true*, unless the file has already been entirely read, in which case it returns *false* and sets *last ← first*. In general, the *ASCII_code* numbers that represent the next line of the file are input into *buffer*[*first*], *buffer*[*first* + 1], ..., *buffer*[*last* − 1]; and the global variable *last* is set equal to *first* plus the length of the line. Trailing blanks are removed from the line; thus, either *last* = *first* (in which case the line was entirely blank) or *buffer*[*last* − 1] ≠ "␣".

An overflow error is given, however, if the normal actions of *input_ln* would make *last* ≥ *buf_size*; this is done so that other parts of TEX can safely look at the contents of *buffer*[*last* + 1] without overstepping the bounds of the *buffer* array. Upon entry to *input_ln*, the condition *first* < *buf_size* will always hold, so that there is always room for an "empty" line.

The variable *max_buf_stack*, which is used to keep track of how large the *buf_size* parameter must be to accommodate the present job, is also kept up to date by *input_ln*.

If the *bypass_eoln* parameter is *true*, *input_ln* will do a *get* before looking at the first character of the line; this skips over an *eoln* that was in *f*↑. The procedure does not do a *get* when it reaches the end of the line; therefore it can be used to acquire input from the user's terminal as well as from ordinary text files.

Standard Pascal says that a file should have *eoln* immediately before *eof*, but TEX needs only a weaker restriction: If *eof* occurs in the middle of a line, the system function *eoln* should return a *true* result (even though *f*↑ will be undefined).

Since the inner loop of *input_ln* is part of TEX's "inner loop"—each character of input comes in at this place—it is wise to reduce system overhead by making use of special routines that read in an entire array of characters at once, if such routines are available. The following code uses standard Pascal to illustrate what needs to be done, but finer tuning is often possible at well-developed Pascal sites.

function *input_ln*(**var** *f* : *alpha_file*; *bypass_eoln* : *boolean*): *boolean*;
　　　　{ inputs the next line or returns *false* }
　var *last_nonblank*: 0 .. *buf_size*;　　{ *last* with trailing blanks removed }
　begin if *bypass_eoln* **then**
　　if ¬*eof*(*f*) **then** *get*(*f*);　　{ input the first character of the line into *f*↑ }
　last ← *first*;　　{ cf. Matthew 19 : 30 }
　if *eof*(*f*) **then** *input_ln* ← *false*
　else begin *last_nonblank* ← *first*;
　　while ¬*eoln*(*f*) **do**
　　　begin if *last* ≥ *max_buf_stack* **then**
　　　　begin *max_buf_stack* ← *last* + 1;
　　　　if *max_buf_stack* = *buf_size* **then** ⟨ Report overflow of the input buffer, and abort 35 ⟩;
　　　　end;
　　　buffer[*last*] ← *xord*[*f*↑]; *get*(*f*); *incr*(*last*);
　　　if *buffer*[*last* − 1] ≠ "␣" **then** *last_nonblank* ← *last*;
　　　end;
　　last ← *last_nonblank*; *input_ln* ← *true*;
　　end;
　end;

32. The user's terminal acts essentially like other files of text, except that it is used both for input and for output. When the terminal is considered an input file, the file variable is called *term_in*, and when it is considered an output file the file variable is *term_out*.

⟨ Global variables 13 ⟩ +≡
term_in: *alpha_file*;　　{ the terminal as an input file }
term_out: *alpha_file*;　　{ the terminal as an output file }

33. Here is how to open the terminal files in Pascal-H. The '/I' switch suppresses the first *get*.

> **define** *t_open_in* ≡ *reset*(*term_in*, ´TTY:´, ´/O/I´)   { open the terminal for text input }
> **define** *t_open_out* ≡ *rewrite*(*term_out*, ´TTY:´, ´/O´)   { open the terminal for text output }

34. Sometimes it is necessary to synchronize the input/output mixture that happens on the user's terminal, and three system-dependent procedures are used for this purpose. The first of these, *update_terminal*, is called when we want to make sure that everything we have output to the terminal so far has actually left the computer's internal buffers and been sent. The second, *clear_terminal*, is called when we wish to cancel any input that the user may have typed ahead (since we are about to issue an unexpected error message). The third, *wake_up_terminal*, is supposed to revive the terminal if the user has disabled it by some instruction to the operating system. The following macros show how these operations can be specified in Pascal-H:

> **define** *update_terminal* ≡ *break*(*term_out*)   { empty the terminal output buffer }
> **define** *clear_terminal* ≡ *break_in*(*term_in*, *true*)   { clear the terminal input buffer }
> **define** *wake_up_terminal* ≡ *do_nothing*   { cancel the user's cancellation of output }

35. We need a special routine to read the first line of TEX input from the user's terminal. This line is different because it is read before we have opened the transcript file; there is sort of a "chicken and egg" problem here. If the user types '\input paper' on the first line, or if some macro invoked by that line does such an \input, the transcript file will be named 'paper.log'; but if no \input commands are performed during the first line of terminal input, the transcript file will acquire its default name 'texput.log'. (The transcript file will not contain error messages generated by the first line before the first \input command.)

The first line is even more special if we are lucky enough to have an operating system that treats TEX differently from a run-of-the-mill Pascal object program. It's nice to let the user start running a TEX job by typing a command line like 'tex paper'; in such a case, TEX will operate as if the first line of input were 'paper', i.e., the first line will consist of the remainder of the command line, after the part that invoked TEX.

The first line is special also because it may be read before TEX has input a format file. In such cases, normal error messages cannot yet be given. The following code uses concepts that will be explained later. (If the Pascal compiler does not support non-local **goto**, the statement '**goto** *final_end*' should be replaced by something that quietly terminates the program.)

⟨ Report overflow of the input buffer, and abort 35 ⟩ ≡
> **if** *format_ident* = 0 **then**
> **begin** *write_ln*(*term_out*, ´Buffer␣size␣exceeded!´); **goto** *final_end*;
> **end**
> **else begin** *cur_input.loc_field* ← *first*; *cur_input.limit_field* ← *last* − 1;
> *overflow*("buffer␣size", *buf_size*);
> **end**

This code is used in sections 31 and 1567.

36. Different systems have different ways to get started. But regardless of what conventions are adopted, the routine that initializes the terminal should satisfy the following specifications:

1) It should open file *term_in* for input from the terminal. (The file *term_out* will already be open for output to the terminal.)
2) If the user has given a command line, this line should be considered the first line of terminal input. Otherwise the user should be prompted with '**', and the first line of input should be whatever is typed in response.
3) The first line of input, which might or might not be a command line, should appear in locations *first* to *last* − 1 of the *buffer* array.
4) The global variable *loc* should be set so that the character to be read next by TEX is in *buffer*[*loc*]. This character should not be blank, and we should have *loc* < *last*.

(It may be necessary to prompt the user several times before a non-blank line comes in. The prompt is '**' instead of the later '*' because the meaning is slightly different: '\input' need not be typed immediately after '**'.)

> **define** *loc* ≡ *cur_input.loc_field*   { location of first unread character in *buffer* }

37. The following program does the required initialization without retrieving a possible command line. It should be clear how to modify this routine to deal with command lines, if the system permits them.

function *init_terminal*: *boolean*;   { gets the terminal input started }
  label *exit*;
  begin *t_open_in*;
  loop begin *wake_up_terminal*; *write*(*term_out*, ´**´); *update_terminal*;
    if ¬*input_ln*(*term_in*, *true*) **then**   { this shouldn't happen }
      begin *write_ln*(*term_out*); *write*(*term_out*, ´!␣End␣of␣file␣on␣the␣terminal...␣why?´);
      init_terminal ← *false*; **return**;
      end;
    loc ← *first*;
    while (*loc* < *last*) ∧ (*buffer*[*loc*] = "␣") **do** *incr*(*loc*);
    if *loc* < *last* **then**
      begin *init_terminal* ← *true*; **return**;   { return unless the line was all blank }
      end;
    write_ln(*term_out*, ´Please␣type␣the␣name␣of␣your␣input␣file.´);
    end;
exit: **end**;

38.   String handling.   Control sequence names and diagnostic messages are variable-length strings of eight-bit characters. Since Pascal does not have a well-developed string mechanism, TEX does all of its string processing by homegrown methods.

Elaborate facilities for dynamic strings are not needed, so all of the necessary operations can be handled with a simple data structure. The array *str_pool* contains all of the (eight-bit) ASCII codes in all of the strings, and the array *str_start* contains indices of the starting points of each string. Strings are referred to by integer numbers, so that string number s comprises the characters *str_pool*[j] for *str_start_macro*[s] $\leq$ $j <$ *str_start_macro*[$s + 1$]. Additional integer variables *pool_ptr* and *str_ptr* indicate the number of entries used so far in *str_pool* and *str_start*, respectively; locations *str_pool*[*pool_ptr*] and *str_start_macro*[*str_ptr*] are ready for the next string to be allocated.

String numbers 0 to 255 are reserved for strings that correspond to single ASCII characters. This is in accordance with the conventions of WEB, which converts single-character strings into the ASCII code number of the single character involved, while it converts other strings into integers and builds a string pool file. Thus, when the string constant "." appears in the program below, WEB converts it into the integer 46, which is the ASCII code for a period, while WEB will convert a string like "hello" into some integer greater than 255. String number 46 will presumably be the single character '.'; but some ASCII codes have no standard visible representation, and TEX sometimes needs to be able to print an arbitrary ASCII character, so the first 256 strings are used to specify exactly what should be printed for each of the 256 possibilities.

Elements of the *str_pool* array must be ASCII codes that can actually be printed; i.e., they must have an *xchr* equivalent in the local character set. (This restriction applies only to preloaded strings, not to those generated dynamically by the user.)

Some Pascal compilers won't pack integers into a single byte unless the integers lie in the range $-128 \ldots 127$. To accommodate such systems we access the string pool only via macros that can easily be redefined.

> **define** $si(\texttt{\#}) \equiv \texttt{\#}$ { convert from *ASCII_code* to *packed_ASCII_code* }
> **define** $so(\texttt{\#}) \equiv \texttt{\#}$ { convert from *packed_ASCII_code* to *ASCII_code* }
> **define** *str_start_macro*($\texttt{\#}$) $\equiv$ *str_start*[($\texttt{\#}$) $-$ *too_big_char*]

⟨ Types in the outer block 18 ⟩ +≡
> *pool_pointer* $= 0 \ldots$ *pool_size*;   { for variables that point into *str_pool* }
> *str_number* $= 0 \ldots$ *max_strings*;   { for variables that point into *str_start* }
> *packed_ASCII_code* $= 0 \ldots$ *biggest_char*;   { elements of *str_pool* array }

39.   ⟨ Global variables 13 ⟩ +≡
str_pool: **packed array** [*pool_pointer*] **of** *packed_ASCII_code*;   { the characters }
str_start: **array** [*str_number*] **of** *pool_pointer*;   { the starting pointers }
pool_ptr: *pool_pointer*;   { first unused position in *str_pool* }
str_ptr: *str_number*;   { number of the current string being created }
init_pool_ptr: *pool_pointer*;   { the starting value of *pool_ptr* }
init_str_ptr: *str_number*;   { the starting value of *str_ptr* }

40.   Several of the elementary string operations are performed using WEB macros instead of Pascal procedures, because many of the operations are done quite frequently and we want to avoid the overhead of procedure calls. For example, here is a simple macro that computes the length of a string.

function *length*(s : *str_number*): *integer*;   { the number of characters in string number s }
> **begin if** ($s \geq$ ″10000) **then** *length* $\leftarrow$ *str_start_macro*($s + 1$) $-$ *str_start_macro*(s)
> **else if** ($s \geq$ ″20) $\wedge$ ($s <$ ″7F) **then** *length* $\leftarrow 1$
>> **else if** ($s \leq$ ″7F) **then** *length* $\leftarrow 3$
>>> **else if** ($s <$ ″100) **then** *length* $\leftarrow 4$
>>>> **else** *length* $\leftarrow 8$
> **end**;

41. The length of the current string is called *cur_length*:

define *cur_length* ≡ (*pool_ptr* − *str_start_macro*(*str_ptr*))

42. Strings are created by appending character codes to *str_pool*. The *append_char* macro, defined here, does not check to see if the value of *pool_ptr* has gotten too high; this test is supposed to be made before *append_char* is used. There is also a *flush_char* macro, which erases the last character appended.

To test if there is room to append *l* more characters to *str_pool*, we shall write *str_room*(*l*), which aborts T_EX and gives an apologetic error message if there isn't enough room.

define *append_char*(#) ≡   { put *ASCII_code* # at the end of *str_pool* }
        begin if (*si*(#) > ″FFFF) **then**
            begin *str_pool*[*pool_ptr*] ← *si*((# − ″10000) **div** ″400 + ″D800); *incr*(*pool_ptr*);
            str_pool[*pool_ptr*] ← *si*((#) **mod** ″400 + ″DC00); *incr*(*pool_ptr*);
            end
        else begin *str_pool*[*pool_ptr*] ← *si*(#); *incr*(*pool_ptr*);
            end;
        end
define *flush_char* ≡ *decr*(*pool_ptr*)   { forget the last character in the pool }
define *str_room*(#) ≡   { make sure that the pool hasn't overflowed }
        begin if *pool_ptr* + # > *pool_size* **then** *overflow*("pool␣size", *pool_size* − *init_pool_ptr*);
        end

43. Once a sequence of characters has been appended to *str_pool*, it officially becomes a string when the function *make_string* is called. This function returns the identification number of the new string as its value.

function *make_string*: *str_number*;   { current string enters the pool }
    begin if *str_ptr* = *max_strings* **then** *overflow*("number␣of␣strings", *max_strings* − *init_str_ptr*);
    incr(*str_ptr*); *str_start_macro*(*str_ptr*) ← *pool_ptr*; *make_string* ← *str_ptr* − 1;
    end;

44. To destroy the most recently made string, we say *flush_string*.

define *flush_string* ≡
            begin *decr*(*str_ptr*); *pool_ptr* ← *str_start_macro*(*str_ptr*);
            end

procedure *append_str*(*s* : *str_number*);   { append an existing string to the current string }
    var *i*: *integer*; *j*: *pool_pointer*;
    begin *i* ← *length*(*s*); *str_room*(*i*); *j* ← *str_start_macro*(*s*);
    while (*i* > 0) **do**
        begin *append_char*(*str_pool*[*j*]); *incr*(*j*); *decr*(*i*);
        end;
    end;

45.   The following subroutine compares string s with another string of the same length that appears in *buffer* starting at position k; the result is *true* if and only if the strings are equal. Empirical tests indicate that *str_eq_buf* is used in such a way that it tends to return *true* about 80 percent of the time.

function *str_eq_buf* (s : *str_number*; k : *integer*): *boolean*;   { test equality of strings }
  label *not_found*;   { loop exit }
  var j: *pool_pointer*;   { running index }
    result: *boolean*;   { result of comparison }
  begin $j \leftarrow str\_start\_macro(s)$;
  while $j < str\_start\_macro(s + 1)$ **do**
    begin if $buffer[k] \geq$ ″10000 **then**
      if $so(str\_pool[j]) \neq$ ″D800 $+ (buffer[k] -$ ″10000$)$ **div** ″400 **then**
        begin $result \leftarrow false$; **goto** *not_found*;
        end
      else if $so(str\_pool[j + 1]) \neq$ ″DC00 $+ (buffer[k] -$ ″10000$)$ **mod** ″400 **then**
          begin $result \leftarrow false$; **goto** *not_found*;
          end
        else *incr*(j)
    else if $so(str\_pool[j]) \neq buffer[k]$ **then**
        begin $result \leftarrow false$; **goto** *not_found*;
        end;
    incr(j); *incr*(k);
    end;
  $result \leftarrow true$;
not_found: $str\_eq\_buf \leftarrow result$;
  end;

46. Here is a similar routine, but it compares two strings in the string pool, and it does not assume that they have the same length.

function $str\_eq\_str(s, t : str\_number)$: $boolean$;   { test equality of strings }
  label not_found;   { loop exit }
  var j, k: $pool\_pointer$;   { running indices }
    $result$: $boolean$;   { result of comparison }
  begin $result \leftarrow false$;
  if $length(s) \neq length(t)$ **then goto** not_found;
  if $(length(s) = 1)$ **then**
    begin if $s < 65536$ **then**
      begin if $t < 65536$ **then**
        begin if $s \neq t$ **then goto** not_found;
        end
      else begin if $s \neq str\_pool[str\_start\_macro(t)]$ **then goto** not_found;
        end;
      end
    else begin if $t < 65536$ **then**
        begin if $str\_pool[str\_start\_macro(s)] \neq t$ **then goto** not_found;
        end
      else begin if $str\_pool[str\_start\_macro(s)] \neq str\_pool[str\_start\_macro(t)]$ **then goto** not_found;
        end;
      end;
    end
  else begin $j \leftarrow str\_start\_macro(s)$; $k \leftarrow str\_start\_macro(t)$;
    while $j < str\_start\_macro(s + 1)$ **do**
      begin if $str\_pool[j] \neq str\_pool[k]$ **then goto** not_found;
      $incr(j)$; $incr(k)$;
      end;
    end;
  $result \leftarrow true$;
not_found: $str\_eq\_str \leftarrow result$;
  end;

47. The initial values of str_pool, str_start, $pool\_ptr$, and str_ptr are computed by the INITEX program, based in part on the information that WEB has output while processing T$_{E}$X.

  init function $get\_strings\_started$: $boolean$;
      { initializes the string pool, but returns $false$ if something goes wrong }
  label $done$, $exit$;
  var m, n: $text\_char$;   { characters input from $pool\_file$ }
    g: str_number;   { garbage }
    a: $integer$;   { accumulator for check sum }
    c: $boolean$;   { check sum has been checked }
  begin $pool\_ptr \leftarrow 0$; $str\_ptr \leftarrow 0$; $str\_start[0] \leftarrow 0$; ⟨ Make the first 256 strings 48 ⟩;
  ⟨ Read the other strings from the TEX.POOL file and return $true$, or give an error message and return
    $false$ 51 ⟩;
$exit$: **end**;
  tini

48. The first 65536 strings will consist of a single character only. But we don't actually make them; they're simulated on the fly.

⟨ Make the first 256 strings 48 ⟩ ≡
  begin $str\_ptr \leftarrow too\_big\_char$; $str\_start\_macro(str\_ptr) \leftarrow pool\_ptr$;
  end

This code is used in section 47.

49. The first 128 strings will contain 95 standard ASCII characters, and the other 33 characters will be printed in three-symbol form like '^^A' unless a system-dependent change is made here. Installations that have an extended character set, where for example $xchr[´32] = ´≠´$, would like string ´32 to be the single character ´32 instead of the three characters ´136, ´136, ´132 (^^Z). On the other hand, even people with an extended character set will want to represent string ´15 by ^^M, since ´15 is *carriage_return*; the idea is to produce visible strings instead of tabs or line-feeds or carriage-returns or bell-rings or characters that are treated anomalously in text files.

  Unprintable characters of codes 128–255 are, similarly, rendered ^^80–^^ff.

  The boolean expression defined here should be *true* unless TEX internal code number k corresponds to a non-troublesome visible symbol in the local character set. An appropriate formula for the extended character set recommended in *The TEXbook* would, for example, be '$k \in [0, ´10 \mathinner{\ldotp\ldotp} ´12, ´14, ´15, ´33, ´177 \mathinner{\ldotp\ldotp} ´377]$'. If character k cannot be printed, and $k < ´200$, then character $k + ´100$ or $k - ´100$ must be printable; moreover, ASCII codes $[´41 \mathinner{\ldotp\ldotp} ´46, ´60 \mathinner{\ldotp\ldotp} ´71, ´136, ´141 \mathinner{\ldotp\ldotp} ´146, ´160 \mathinner{\ldotp\ldotp} ´171]$ must be printable. Thus, at least 80 printable characters are needed.

50. When the WEB system program called TANGLE processes the TEX.WEB description that you are now reading, it outputs the Pascal program TEX.PAS and also a string pool file called TEX.POOL. The INITEX program reads the latter file, where each string appears as a two-digit decimal length followed by the string itself, and the information is recorded in TEX's string memory.

⟨ Global variables 13 ⟩ +≡
  init $pool\_file$: $alpha\_file$;   { the string-pool file output by TANGLE }
  tini

51.   **define** $bad\_pool(\#) \equiv$
        begin $wake\_up\_terminal$; $write\_ln(term\_out, \#)$; $a\_close(pool\_file)$; $get\_strings\_started \leftarrow false$;
        return;
        end

⟨ Read the other strings from the TEX.POOL file and return *true*, or give an error message and return
    false 51 ⟩ ≡
  $name\_of\_file \leftarrow pool\_name$;   { we needn't set *name_length* }
  if $a\_open\_in(pool\_file)$ **then**
    begin $c \leftarrow false$;
    repeat ⟨ Read one string, but return *false* if the string memory space is getting too tight for
        comfort 52 ⟩;
    until c;
    $a\_close(pool\_file)$; $get\_strings\_started \leftarrow true$;
    end
  else $bad\_pool(´!_{⊔}I_{⊔}can´´t_{⊔}read_{⊔}TEX.POOL.´)$

This code is used in section 47.

52. ⟨ Read one string, but return *false* if the string memory space is getting too tight for comfort 52 ⟩ ≡
 begin if *eof*(*pool_file*) **then** *bad_pool*(´!␣TEX.POOL␣has␣no␣check␣sum.´);
 read(*pool_file*, *m*, *n*); { read two digits of string length }
 if *m* = ´*´ **then** ⟨ Check the pool check sum 53 ⟩
 else begin if (*xord*[*m*] < "0") ∨ (*xord*[*m*] > "9") ∨ (*xord*[*n*] < "0") ∨ (*xord*[*n*] > "9") **then**
  bad_pool(´!␣TEX.POOL␣line␣doesn´´t␣begin␣with␣two␣digits.´);
 l ← *xord*[*m*] ∗ 10 + *xord*[*n*] − "0" ∗ 11; { compute the length }
 if *pool_ptr* + *l* + *string_vacancies* > *pool_size* **then** *bad_pool*(´!␣You␣have␣to␣increase␣POOLSIZE.´);
 for *k* ← 1 **to** *l* **do**
  begin if *eoln*(*pool_file*) **then** *m* ← ´␣´ **else** *read*(*pool_file*, *m*);
  append_char(*xord*[*m*]);
  end;
 read_ln(*pool_file*); *g* ← *make_string*;
 end;
 end

This code is used in section 51.

53. The WEB operation @$ denotes the value that should be at the end of this TEX.POOL file; any other
value means that the wrong pool file has been loaded.

⟨ Check the pool check sum 53 ⟩ ≡
 begin *a* ← 0; *k* ← 1;
 loop begin if (*xord*[*n*] < "0") ∨ (*xord*[*n*] > "9") **then**
  bad_pool(´!␣TEX.POOL␣check␣sum␣doesn´´t␣have␣nine␣digits.´);
 a ← 10 ∗ *a* + *xord*[*n*] − "0";
 if *k* = 9 **then goto** *done*;
 incr(*k*); *read*(*pool_file*, *n*);
 end;
done: **if** *a* ≠ @$ **then** *bad_pool*(´!␣TEX.POOL␣doesn´´t␣match;␣TANGLE␣me␣again.´);
 c ← *true*;
 end

This code is used in section 52.

54.   On-line and off-line printing.   Messages that are sent to a user's terminal and to the transcript-log file are produced by several '*print*' procedures. These procedures will direct their output to a variety of places, based on the setting of the global variable *selector*, which has the following possible values:

term_and_log, the normal setting, prints on the terminal and on the transcript file.

log_only, prints only on the transcript file.

term_only, prints only on the terminal.

no_print, doesn't print at all. This is used only in rare cases before the transcript file is open.

pseudo, puts output into a cyclic buffer that is used by the *show_context* routine; when we get to that routine we shall discuss the reasoning behind this curious mode.

new_string, appends the output to the current string in the string pool.

0 to 15, prints on one of the sixteen files for \write output.

The symbolic names '*term_and_log*', etc., have been assigned numeric codes that satisfy the convenient relations $no\_print + 1 = term\_only$, $no\_print + 2 = log\_only$, $term\_only + 2 = log\_only + 1 = term\_and\_log$.

Three additional global variables, *tally* and *term_offset* and *file_offset*, record the number of characters that have been printed since they were most recently cleared to zero. We use *tally* to record the length of (possibly very long) stretches of printing; *term_offset* and *file_offset*, on the other hand, keep track of how many characters have appeared so far on the current line that has been output to the terminal or to the transcript file, respectively.

> **define** $no\_print = 16$ { *selector* setting that makes data disappear }
> **define** $term\_only = 17$ { printing is destined for the terminal only }
> **define** $log\_only = 18$ { printing is destined for the transcript file only }
> **define** $term\_and\_log = 19$ { normal *selector* setting }
> **define** $pseudo = 20$ { special *selector* setting for *show_context* }
> **define** $new\_string = 21$ { printing is deflected to the string pool }
> **define** $max\_selector = 21$ { highest selector setting }

⟨ Global variables 13 ⟩ +≡

log_file: *alpha_file*;   { transcript of TEX session }

selector: $0 .. max\_selector$;   { where to print a message }

dig: **array** $[0 .. 22]$ **of** $0 .. 15$;   { digits in a number being output }

tally: *integer*;   { the number of characters recently printed }

term_offset: $0 .. max\_print\_line$;   { the number of characters on the current terminal line }

file_offset: $0 .. max\_print\_line$;   { the number of characters on the current file line }

trick_buf: **array** $[0 .. error\_line]$ **of** *ASCII_code*;   { circular buffer for pseudoprinting }

trick_count: *integer*;   { threshold for pseudoprinting, explained later }

first_count: *integer*;   { another variable for pseudoprinting }

55.   ⟨ Initialize the output routines 55 ⟩ ≡

$selector \leftarrow term\_only$; $tally \leftarrow 0$; $term\_offset \leftarrow 0$; $file\_offset \leftarrow 0$;

See also sections 65, 563, and 568.

This code is used in section 1386.

56.   Macro abbreviations for output to the terminal and to the log file are defined here for convenience. Some systems need special conventions for terminal output, and it is possible to adhere to those conventions by changing *wterm*, *wterm_ln*, and *wterm_cr* in this section.

> **define** $wterm(\#) \equiv write(term\_out, \#)$
> **define** $wterm\_ln(\#) \equiv write\_ln(term\_out, \#)$
> **define** $wterm\_cr \equiv write\_ln(term\_out)$
> **define** $wlog(\#) \equiv write(log\_file, \#)$
> **define** $wlog\_ln(\#) \equiv write\_ln(log\_file, \#)$
> **define** $wlog\_cr \equiv write\_ln(log\_file)$

57.   To end a line of text output, we call *print_ln*.

⟨ Basic printing procedures 57 ⟩ ≡

procedure *print_ln*;   { prints an end-of-line }
  begin case *selector* **of**
  term_and_log: **begin** *wterm_cr*; *wlog_cr*; *term_offset* ← 0; *file_offset* ← 0;
    end;
  log_only: **begin** *wlog_cr*; *file_offset* ← 0;
    end;
  term_only: **begin** *wterm_cr*; *term_offset* ← 0;
    end;
  no_print, *pseudo*, *new_string*: *do_nothing*;
  othercases *write_ln*(*write_file*[*selector*])
  endcases;
  end;   { *tally* is not affected }

See also sections 58, 59, 63, 66, 67, 68, 69, 292, 293, 553, 741, 1415, and 1633.

This code is used in section 4.

58. The *print_raw_char* procedure sends one character to the desired destination, using the *xchr* array to map it into an external character compatible with *input_ln*. All printing comes through *print_ln*, *print_char* or *print_visible_char*. When printing a multi-byte character, the boolean parameter *incr_offset* is set *false* except for the very last byte, to avoid calling *print_ln* in the middle of such character.

⟨ Basic printing procedures 57 ⟩ +≡
procedure *print_raw_char*(*s* : *UnicodeScalar*; *incr_offset* : *boolean*);   { prints a single character }
  label *exit*;   { label is not used but nonetheless kept (for other changes?) }
  begin case *selector* **of**
  term_and_log: **begin** *wterm*(*xchr*[*s*]); *wlog*(*xchr*[*s*]);
    if *incr_offset* **then**
      begin *incr*(*term_offset*); *incr*(*file_offset*);
      end;
    if *term_offset* = *max_print_line* **then**
      begin *wterm_cr*; *term_offset* ← 0;
      end;
    if *file_offset* = *max_print_line* **then**
      begin *wlog_cr*; *file_offset* ← 0;
      end;
    end;
  log_only: **begin** *wlog*(*xchr*[*s*]);
    if *incr_offset* **then** *incr*(*file_offset*);
    if *file_offset* = *max_print_line* **then** *print_ln*;
    end;
  term_only: **begin** *wterm*(*xchr*[*s*]);
    if *incr_offset* **then** *incr*(*term_offset*);
    if *term_offset* = *max_print_line* **then** *print_ln*;
    end;
  no_print: *do_nothing*;
  pseudo: **if** *tally* < *trick_count* **then** *trick_buf*[*tally* **mod** *error_line*] ← *s*;
  new_string: **begin if** *pool_ptr* < *pool_size* **then** *append_char*(*s*);
    end;   { we drop characters if the string space is full }
  othercases *write*(*write_file*[*selector*], *xchr*[*s*])
  endcases;
  incr(*tally*);
exit: **end**;

59. The *print_char* procedure sends one character to the desired destination. Control sequence names, file names and string constructed with `\string` might contain *ASCII_code* values that can't be printed using *print_raw_char*. These characters will be printed in three- or four-symbol form like '^^A' or '^^e4', unless the -8bit option is enabled. Output that goes to the terminal and/or log file is treated differently when it comes to determining whether a character is printable.

define *print_visible_char*(#) ≡ *print_raw_char*(#, *true*)
define *print_lc_hex*(#) ≡ *l* ← #;

    $native\_text \leftarrow xmalloc(native\_text\_size * sizeof(UTF16\_code));$

63. An entire string is output by calling *print*. Note that if we are outputting the single standard ASCII character c, we could call *print*("c"), since "c" = 99 is the number of a single-character string, as explained above. But *print_char*("c") is quicker, so TEX goes directly to the *print_char* routine when it knows that this is safe. (The present implementation assumes that it is always safe to print a visible ASCII character.)

⟨Basic printing procedures 57⟩ +≡
procedure *print*(*s* : *integer*);   {prints string *s*}
  label *exit*;
  var *j*: *pool_pointer*;   {current character code position}
    nl: *integer*;   {new-line character to restore}
  begin if *s* ≥ *str_ptr* **then** *s* ← "???"   {this can't happen}
  else if *s* < *biggest_char* **then**
      if *s* < 0 **then** *s* ← "???"   {can't happen}
      else begin if *selector* > *pseudo* **then**
          begin *print_char*(*s*); **return**;   {internal strings are not expanded}
          end;
        if (⟨Character *s* is the current new-line character 270⟩) **then**
          if *selector* < *pseudo* **then**
            begin *print_ln*; **return**;
            end;
        nl ← *new_line_char*; *new_line_char* ← −1; *print_char*(*s*); *new_line_char* ← *nl*; **return**;
      end;
  j ← *str_start_macro*(*s*);
  while *j* < *str_start_macro*(*s* + 1) **do**
    begin if (*so*(*str_pool*[*j*]) ≥ ˝D800) ∧ (*so*(*str_pool*[*j*]) ≤ ˝DBFF) ∧ (*j* + 1 <
        str_start_macro(*s* + 1)) ∧ (*so*(*str_pool*[*j* + 1]) ≥ ˝DC00) ∧ (*so*(*str_pool*[*j* + 1]) ≤ ˝DFFF) **then**
      begin *print_char*(˝10000 + (*so*(*str_pool*[*j*]) − ˝D800) ∗ ˝400 + *so*(*str_pool*[*j* + 1]) − ˝DC00); *j* ← *j* + 2;
      end
    else begin *print_char*(*so*(*str_pool*[*j*])); *incr*(*j*);
      end;
    end;
exit: **end**;

64. Old versions of TEX needed a procedure called *slow_print* whose function is now subsumed by *print* and the new functionality of *print_char* and *print_visible_char*. We retain the old name *slow_print* here as a possible aid to future software archæologists.

  define *slow_print* ≡ *print*

65. Here is the very first thing that TEX prints: a headline that identifies the version number and format package. The *term_offset* variable is temporarily incorrect, but the discrepancy is not serious since we assume that this part of the program is system dependent.

⟨Initialize the output routines 55⟩ +≡
  wterm(*banner*);
  if *format_ident* = 0 **then** *wterm_ln*(´␣(no␣format␣preloaded)´)
  else begin *slow_print*(*format_ident*); *print_ln*;
    end;
  update_terminal;

66.   The procedure *print_nl* is like *print*, but it makes sure that the string appears at the beginning of a new line.

⟨ Basic printing procedures 57 ⟩ +≡

procedure *print_nl*(*s* : *str_number*);   { prints string *s* at beginning of line }
  begin if ((*term_offset* > 0) ∧ (*odd*(*selector*))) ∨ ((*file_offset* > 0) ∧ (*selector* ≥ *log_only*)) **then** *print_ln*;
  print(*s*);
  end;

67.   The procedure *print_esc* prints a string that is preceded by the user's escape character (which is usually a backslash).

⟨ Basic printing procedures 57 ⟩ +≡

procedure *print_esc*(*s* : *str_number*);   { prints escape character, then *s* }
  var *c*: *integer*;   { the escape character code }
  begin ⟨ Set variable *c* to the current escape character 269 ⟩;
  if *c* ≥ 0 **then**
    if *c* ≤ *biggest_usv* **then** *print_char*(*c*);
  slow_print(*s*);
  end;

68.   An array of digits in the range 0 . . 15 is printed by *print_the_digs*.

⟨ Basic printing procedures 57 ⟩ +≡

procedure *print_the_digs*(*k* : *eight_bits*);   { prints *dig*[*k* − 1] . . . *dig*[0] }
  begin while *k* > 0 **do**
    begin *decr*(*k*);
    if *dig*[*k*] < 10 **then** *print_char*("0" + *dig*[*k*])
    else *print_char*("A" − 10 + *dig*[*k*]);
    end;
  end;

69.   The following procedure, which prints out the decimal representation of a given integer *n*, has been written carefully so that it works properly if *n* = 0 or if (−*n*) would cause overflow. It does not apply **mod** or **div** to negative arguments, since such operations are not implemented consistently by all Pascal compilers.

⟨ Basic printing procedures 57 ⟩ +≡

procedure *print_int*(*n* : *integer*);   { prints an integer in decimal form }
  var *k*: 0 . . 23;   { index to current digit; we assume that |*n*| < 10^{23} }
    m: *integer*;   { used to negate *n* in possibly dangerous cases }
  begin *k* ← 0;
  if *n* < 0 **then**
    begin *print_char*("−");
    if *n* > −100000000 **then** *negate*(*n*)
    else begin *m* ← −1 − *n*; *n* ← *m* **div** 10; *m* ← (*m* **mod** 10) + 1; *k* ← 1;
      if *m* < 10 **then** *dig*[0] ← *m*
      else begin *dig*[0] ← 0; *incr*(*n*);
        end;
      end;
    end;
  repeat *dig*[*k*] ← *n* **mod** 10; *n* ← *n* **div** 10; *incr*(*k*);
  until *n* = 0;
  print_the_digs(*k*);
  end;

70. Here is a trivial procedure to print two digits; it is usually called with a parameter in the range $0 \le n \le 99$.

procedure *print_two*(*n* : *integer*);   { prints two least significant digits }
  begin $n \leftarrow abs(n) \bmod 100$; *print_char*("0" + ($n$ **div** 10)); *print_char*("0" + (n **mod** 10));
  end;

71. Hexadecimal printing of nonnegative integers is accomplished by *print_hex*.

procedure *print_hex*(*n* : *integer*);   { prints a positive integer in hexadecimal form }
  var *k*: 0 . . 22;   { index to current digit; we assume that $0 \le n < 16^{22}$ }
  begin $k \leftarrow 0$; *print_char*("""");
  repeat *dig*[*k*] $\leftarrow n \bmod 16$; $n \leftarrow n$ **div** 16; *incr*(*k*);
  until $n = 0$;
  print_the_digs(*k*);
  end;

72. Old versions of T$_E$X needed a procedure called *print_ASCII* whose function is now subsumed by *print*. We retain the old name here as a possible aid to future software archæologists.

  define *print_ASCII* $\equiv$ *print*

73. Roman numerals are produced by the *print_roman_int* routine. Readers who like puzzles might enjoy trying to figure out how this tricky code works; therefore no explanation will be given. Notice that 1990 yields mcmxc, not mxm.

procedure *print_roman_int*(*n* : *integer*);
  label *exit*;
  var *j*, *k*: *pool_pointer*;   { mysterious indices into *str_pool* }
    u, *v*: *nonnegative_integer*;   { mysterious numbers }
  begin $j \leftarrow$ *str_start_macro*("m2d5c2l5x2v5i"); $v \leftarrow 1000$;
  loop begin while $n \ge v$ **do**
    begin *print_char*(*so*(*str_pool*[*j*])); $n \leftarrow n - v$;
    end;
  if $n \le 0$ **then** **return**;   { nonpositive input produces no output }
  $k \leftarrow j + 2$; $u \leftarrow v$ **div** (*so*(*str_pool*[*k* − 1]) − "0");
  if *str_pool*[*k* − 1] = *si*("2") **then**
    begin $k \leftarrow k + 2$; $u \leftarrow u$ **div** (*so*(*str_pool*[*k* − 1]) − "0");
    end;
  if $n + u \ge v$ **then**
    begin *print_char*(*so*(*str_pool*[*k*])); $n \leftarrow n + u$;
    end
  else begin $j \leftarrow j + 2$; $v \leftarrow v$ **div** (*so*(*str_pool*[*j* − 1]) − "0");
    end;
    end;
exit: **end**;

74. The *print* subroutine will not print a string that is still being created. The following procedure will.

procedure *print_current_string*;   { prints a yet-unmade string }
  var *j*: *pool_pointer*;   { points to current character code }
  begin $j \leftarrow$ *str_start_macro*(*str_ptr*);
  while $j <$ *pool_ptr* **do**
  begin *print_char*(*so*(*str_pool*[*j*])); *incr*(*j*);
    end;
  end;

75.   Here is a procedure that asks the user to type a line of input, assuming that the *selector* setting is either *term_only* or *term_and_log*. The input is placed into locations *first* through *last* − 1 of the *buffer* array, and echoed on the transcript file if appropriate.

This procedure is never called when *interaction* < *scroll_mode*.

> **define** *prompt_input*(#) ≡
>> **begin** *wake_up_terminal*; *print*(#); *term_input*;
>> **end**   { prints a string and gets a line of input }

procedure *term_input*;   { gets a line from the terminal }
  var *k*: 0 . . *buf_size*;   { index into *buffer* }
  begin *update_terminal*;   { now the user sees the prompt for sure }
  if ¬*input_ln*(*term_in*, *true*) **then** *fatal_error*("End␣of␣file␣on␣the␣terminal!");
  term_offset ← 0;   { the user's line ended with ⟨return⟩ }
  decr(*selector*);   { prepare to echo the input }
  if *last* ≠ *first* **then**
     for *k* ← *first* **to** *last* − 1 **do** *print*(*buffer*[*k*]);
  print_ln; *incr*(*selector*);   { restore previous status }
  end;

76. Reporting errors.   When something anomalous is detected, TEX typically does something like this:

$$print\_err(\texttt{"Something}_\sqcup\texttt{anomalous}_\sqcup\texttt{has}_\sqcup\texttt{been}_\sqcup\texttt{detected"});$$
$$help3(\texttt{"This}_\sqcup\texttt{is}_\sqcup\texttt{the}_\sqcup\texttt{first}_\sqcup\texttt{line}_\sqcup\texttt{of}_\sqcup\texttt{my}_\sqcup\texttt{offer}_\sqcup\texttt{to}_\sqcup\texttt{help."})$$
$$(\texttt{"This}_\sqcup\texttt{is}_\sqcup\texttt{the}_\sqcup\texttt{second}_\sqcup\texttt{line.}_\sqcup\texttt{I´m}_\sqcup\texttt{trying}_\sqcup\texttt{to"})$$
$$(\texttt{"explain}_\sqcup\texttt{the}_\sqcup\texttt{best}_\sqcup\texttt{way}_\sqcup\texttt{for}_\sqcup\texttt{you}_\sqcup\texttt{to}_\sqcup\texttt{proceed."});$$
$$error;$$

A two-line help message would be given using *help2*, etc.; these informal helps should use simple vocabulary that complements the words used in the official error message that was printed. (Outside the U.S.A., the help messages should preferably be translated into the local vernacular. Each line of help is at most 60 characters long, in the present implementation, so that *max_print_line* will not be exceeded.)

The *print_err* procedure supplies a '!' before the official message, and makes sure that the terminal is awake if a stop is going to occur. The *error* procedure supplies a '.' after the official message, then it shows the location of the error; and if *interaction* = *error_stop_mode*, it also enters into a dialog with the user, during which time the help message may be printed.

77.   The global variable *interaction* has four settings, representing increasing amounts of user interaction:

define *batch_mode* = 0   { omits all stops and omits terminal output }
define *nonstop_mode* = 1   { omits all stops }
define *scroll_mode* = 2   { omits error stops }
define *error_stop_mode* = 3   { stops at every opportunity to interact }
define *print_err*(#) ≡
　　　　begin if *interaction* = *error_stop_mode* **then** *wake_up_terminal*;
　　　　print_nl(`"!␣"`); *print*(#);
　　　　end

⟨ Global variables 13 ⟩ +≡
interaction: *batch_mode* .. *error_stop_mode*;   { current level of interaction }

78.   ⟨ Set initial values of key variables 23 ⟩ +≡
　interaction ← *error_stop_mode*;

79.   TEX is careful not to call *error* when the print *selector* setting might be unusual. The only possible values of *selector* at the time of error messages are

no_print (when *interaction* = *batch_mode* and *log_file* not yet open);
term_only (when *interaction* > *batch_mode* and *log_file* not yet open);
log_only (when *interaction* = *batch_mode* and *log_file* is open);
term_and_log (when *interaction* > *batch_mode* and *log_file* is open).

⟨ Initialize the print *selector* based on *interaction* 79 ⟩ ≡
　if *interaction* = *batch_mode* **then** *selector* ← *no_print* **else** *selector* ← *term_only*
This code is used in sections 1319 and 1391.

80.   A global variable *deletions_allowed* is set *false* if the *get_next* routine is active when *error* is called; this ensures that *get_next* and related routines like *get_token* will never be called recursively. A similar interlock is provided by *set_box_allowed*.

The global variable *history* records the worst level of error that has been detected. It has four possible values: *spotless*, *warning_issued*, *error_message_issued*, and *fatal_error_stop*.

Another global variable, *error_count*, is increased by one when an *error* occurs without an interactive dialog, and it is reset to zero at the end of every paragraph. If *error_count* reaches 100, T$_E$X decides that there is no point in continuing further.

define *spotless* = 0   { *history* value when nothing has been amiss yet }
define *warning_issued* = 1   { *history* value when *begin_diagnostic* has been called }
define *error_message_issued* = 2   { *history* value when *error* has been called }
define *fatal_error_stop* = 3   { *history* value when termination was premature }

⟨ Global variables 13 ⟩ +≡
deletions_allowed: *boolean*;   { is it safe for *error* to call *get_token*? }
set_box_allowed: *boolean*;   { is it safe to do a \setbox assignment? }
history: *spotless* .. *fatal_error_stop*;   { has the source input been clean so far? }
error_count: −1 .. 100;   { the number of scrolled errors since the last paragraph ended }

81.   The value of *history* is initially *fatal_error_stop*, but it will be changed to *spotless* if T$_E$X survives the initialization process.

⟨ Set initial values of key variables 23 ⟩ +≡
  deletions_allowed ← *true*; *set_box_allowed* ← *true*; *error_count* ← 0;   { *history* is initialized elsewhere }

82.   Since errors can be detected almost anywhere in T$_E$X, we want to declare the error procedures near the beginning of the program. But the error procedures in turn use some other procedures, which need to be declared *forward* before we get to *error* itself.

It is possible for *error* to be called recursively if some error arises when *get_token* is being used to delete a token, and/or if some fatal error occurs while T$_E$X is trying to fix a non-fatal one. But such recursion is never more than two levels deep.

⟨ Error handling procedures 82 ⟩ ≡

procedure *clear_for_error_prompt*; *forward*;
procedure *give_err_help*; *forward*;
debug   procedure *debug_help*; *forward*; **gubed**

See also sections 85, 86, 97, 98, 99, and 1455.

This code is used in section 4.

83.   Individual lines of help are recorded in the array *help_line*, which contains entries in positions 0 . . (*help_ptr* − 1). They should be printed in reverse order, i.e., with *help_line*[0] appearing last.

define *hlp1*(#) ≡ *help_line*[0] ← #; **end**
define *hlp2*(#) ≡ *help_line*[1] ← #; *hlp1*
define *hlp3*(#) ≡ *help_line*[2] ← #; *hlp2*
define *hlp4*(#) ≡ *help_line*[3] ← #; *hlp3*
define *hlp5*(#) ≡ *help_line*[4] ← #; *hlp4*
define *hlp6*(#) ≡ *help_line*[5] ← #; *hlp5*
define *help0* ≡ *help_ptr* ← 0   { sometimes there might be no help }
define *help1* ≡ **begin** *help_ptr* ← 1; *hlp1*   { use this with one help line }
define *help2* ≡ **begin** *help_ptr* ← 2; *hlp2*   { use this with two help lines }
define *help3* ≡ **begin** *help_ptr* ← 3; *hlp3*   { use this with three help lines }
define *help4* ≡ **begin** *help_ptr* ← 4; *hlp4*   { use this with four help lines }
define *help5* ≡ **begin** *help_ptr* ← 5; *hlp5*   { use this with five help lines }
define *help6* ≡ **begin** *help_ptr* ← 6; *hlp6*   { use this with six help lines }

⟨ Global variables 13 ⟩ +≡
help_line: **array** [0 . . 5] **of** *str_number*;   { helps for the next *error* }
help_ptr: 0 . . 6;   { the number of help lines present }
use_err_help: *boolean*;   { should the *err_help* list be shown? }

84.   ⟨ Set initial values of key variables 23 ⟩ +≡
   help_ptr ← 0; *use_err_help* ← *false*;

85.   The *jump_out* procedure just cuts across all active procedure levels and goes to *end_of_TEX*. This is the only nontrivial **goto** statement in the whole program. It is used when there is no recovery from a particular error.

   Some Pascal compilers do not implement non-local **goto** statements. In such cases the body of *jump_out* should simply be '*close_files_and_terminate*;' followed by a call on some system procedure that quietly terminates the program.

⟨ Error handling procedures 82 ⟩ +≡
procedure *jump_out*;
   begin goto *end_of_TEX*;
   end;

86.   Here now is the general *error* routine.

⟨ Error handling procedures 82 ⟩ +≡
procedure *error*;   { completes the job of error reporting }
   label *continue*, *exit*;
   var *c*: *UnicodeScalar*;   { what the user types }
      s1, *s2*, *s3*, *s4*: *integer*;   { used to save global variables when deleting tokens }
   begin if *history* < *error_message_issued* **then** *history* ← *error_message_issued*;
   print_char("."); *show_context*;
   if *interaction* = *error_stop_mode* **then** ⟨ Get user's advice and **return** 87 ⟩;
   incr(*error_count*);
   if *error_count* = 100 **then**
      begin *print_nl*("(That␣makes␣100␣errors;␣please␣try␣again.)"); *history* ← *fatal_error_stop*;
      jump_out;
      end;
   ⟨ Put help message on the transcript file 94 ⟩;
exit: **end**;

87. ⟨Get user's advice and **return** 87⟩ ≡
  loop begin *continue*: **if** *interaction* ≠ *error_stop_mode* **then return**;
    clear_for_error_prompt; *prompt_input*("?␣");
    if *last* = *first* **then return**;

    end;
  othercases *do_nothing*
  endcases;
  ⟨Print the menu of available options 89⟩
This code is used in section 87.

89.   ⟨Print the menu of available options 89⟩ ≡
  begin *print*("Type␣<return>␣to␣proceed,␣S␣to␣scroll␣future␣error␣messages,");
  print_nl("R␣to␣run␣without␣stopping,␣Q␣to␣run␣quietly,");
  print_nl("I␣to␣insert␣something,␣");
  if *base_ptr* > 0 **then**
    if *input_stack*[*base_ptr*].*name_field* ≥ 256 **then** *print*("E␣to␣edit␣your␣file,");
  if *deletions_allowed* **then**
    print_nl("1␣or␣...␣or␣9␣to␣ignore␣the␣next␣1␣to␣9␣tokens␣of␣input,");
  print_nl("H␣for␣help,␣X␣to␣quit.");
  end

This code is used in section 88.

90. Here the author of TEX apologizes for making use of the numerical relation between "Q", "R", "S", and the desired interaction settings *batch_mode*, *nonstop_mode*, *scroll_mode*.

⟨Change the interaction level and **return** 90⟩ ≡
  begin *error_count* ← 0; *interaction* ← *batch_mode* + *c* − "Q"; *print*("OK,␣entering␣");
  case *c* **of**
  "Q": **begin** *print_esc*("batchmode"); *decr*(*selector*);
    end;
  "R": *print_esc*("nonstopmode");
  "S": *print_esc*("scrollmode");
  end; { there are no other cases }
  print("..."); *print_ln*; *update_terminal*; **return**;
  end

This code is used in section 88.

91. When the following code is executed, *buffer*[(*first* + 1) .. (*last* − 1)] may contain the material inserted by the user; otherwise another prompt will be given. In order to understand this part of the program fully, you need to be familiar with TEX's input stacks.

⟨Introduce new material from the terminal and **return** 91⟩ ≡
  begin *begin_file_reading*; { enter a new syntactic level for terminal input }
    { now *state* = *mid_line*, so an initial blank space will count as a blank }
  if *last* > *first* + 1 **then**
    begin *loc* ← *first* + 1; *buffer*[*first*] ← "␣";
    end
  else begin *prompt_input*("insert>"); *loc* ← *first*;
    end;
  first ← *last*; *cur_input.limit_field* ← *last* − 1; { no *end_line_char* ends this line }
  return;
  end

This code is used in section 88.

92. We allow deletion of up to 99 tokens at a time.

⟨Delete *c* − "0" tokens and **goto** *continue* 92⟩ ≡
  begin *s1* ← *cur_tok*; *s2* ← *cur_cmd*; *s3* ← *cur_chr*; *s4* ← *align_state*; *align_state* ← 1000000;
  OK_to_interrupt ← *false*;
  if (*last* > *first* + 1) ∧ (*buffer*[*first* + 1] ≥ "0") ∧ (*buffer*[*first* + 1] ≤ "9") **then**
    c ← *c* ∗ 10 + *buffer*[*first* + 1] − "0" ∗ 11
  else *c* ← *c* − "0";
  while *c* > 0 **do**
    begin *get_token*; { one-level recursive call of *error* is possible }
    decr(*c*);
    end;
  cur_tok ← *s1*; *cur_cmd* ← *s2*; *cur_chr* ← *s3*; *align_state* ← *s4*; *OK_to_interrupt* ← *true*;
  help2("I␣have␣just␣deleted␣some␣text,␣as␣you␣asked.")
  ("You␣can␣now␣delete␣more,␣or␣insert,␣or␣whatever."); *show_context*; **goto** *continue*;
  end

This code is used in section 88.

93. ⟨ Print the help information and **goto** *continue* 93 ⟩ ≡
  begin if *use_err_help* **then**
    begin *give_err_help*; *use_err_help* ← *false*;
    end
  else begin if *help_ptr* = 0 **then** *help2* ("Sorry,␣I␣don´t␣know␣how␣to␣help␣in␣this␣situation.")
      ("Maybe␣you␣should␣try␣asking␣a␣human?");
    repeat *decr*(*help_ptr*); *print*(*help_line*[*help_ptr*]); *print_ln*;
    until *help_ptr* = 0;
    end;
  help4 ("Sorry,␣I␣already␣gave␣what␣help␣I␣could...")
  ("Maybe␣you␣should␣try␣asking␣a␣human?")
  ("An␣error␣might␣have␣occurred␣before␣I␣noticed␣any␣problems.")
  ("``If␣all␣else␣fails,␣read␣the␣instructions.´´");
  goto *continue*;
  end

This code is used in section 88.

94. ⟨ Put help message on the transcript file 94 ⟩ ≡
  if *interaction* > *batch_mode* **then** *decr*(*selector*);   { avoid terminal output }
  if *use_err_help* **then**
    begin *print_ln*; *give_err_help*;
    end
  else while *help_ptr* > 0 **do**
      begin *decr*(*help_ptr*); *print_nl*(*help_line*[*help_ptr*]);
      end;
  print_ln;
  if *interaction* > *batch_mode* **then** *incr*(*selector*);   { re-enable terminal output }
  print_ln

This code is used in section 86.

95.   A dozen or so error messages end with a parenthesized integer, so we save a teeny bit of program space
by declaring the following procedure:

procedure *int_error*(*n* : *integer*);
  begin *print*("␣("); *print_int*(*n*); *print_char*(")"); *error*;
  end;

96.   In anomalous cases, the print selector might be in an unknown state; the following subroutine is called
to fix things just enough to keep running a bit longer.

procedure *normalize_selector*;
  begin if *log_opened* **then** *selector* ← *term_and_log*
  else *selector* ← *term_only*;
  if *job_name* = 0 **then** *open_log_file*;
  if *interaction* = *batch_mode* **then** *decr*(*selector*);
  end;

97.   The following procedure prints T$_{E}$X's last words before dying.

> **define** *succumb* ≡
> > **begin if** *interaction* = *error_stop_mode* **then** *interaction* ← *scroll_mode*;
> > > { no more interaction }
> >
> > **if** *log_opened* **then** *error*;
> > **debug if** *interaction* > *batch_mode* **then** *debug_help*;
> > **gubed**
> > *history* ← *fatal_error_stop*; *jump_out*;   { irrecoverable error }
> > **end**

⟨ Error handling procedures 82 ⟩ +≡
procedure *fatal_error*(*s* : *str_number*);   { prints *s*, and that's it }
  begin *normalize_selector*;
  print_err("Emergency␣stop"); *help1*(*s*); *succumb*;
  end;

98.   Here is the most dreaded error message.

⟨ Error handling procedures 82 ⟩ +≡
procedure *overflow*(*s* : *str_number*; *n* : *integer*);   { stop due to finiteness }
  begin *normalize_selector*; *print_err*("TeX␣capacity␣exceeded,␣sorry␣["); *print*(*s*); *print_char*("=");
  print_int(*n*); *print_char*("]"); *help2*("If␣you␣really␣absolutely␣need␣more␣capacity,")
  ("you␣can␣ask␣a␣wizard␣to␣enlarge␣me."); *succumb*;
  end;

99.   The program might sometime run completely amok, at which point there is no choice but to stop. If no previous error has been detected, that's bad news; a message is printed that is really intended for the T$_{E}$X maintenance person instead of the user (unless the user has been particularly diabolical). The index entries for 'this can't happen' may help to pinpoint the problem.

⟨ Error handling procedures 82 ⟩ +≡
procedure *confusion*(*s* : *str_number*);   { consistency check violated; *s* tells where }
  begin *normalize_selector*;
  if *history* < *error_message_issued* **then**
    begin *print_err*("This␣can´t␣happen␣("); *print*(*s*); *print_char*(")");
    help1("I´m␣broken.␣Please␣show␣this␣to␣someone␣who␣can␣fix␣can␣fix");
    end
  else begin *print_err*("I␣can´t␣go␣on␣meeting␣you␣like␣this");
    help2("One␣of␣your␣faux␣pas␣seems␣to␣have␣wounded␣me␣deeply...")
    ("in␣fact,␣I´m␣barely␣conscious.␣Please␣fix␣it␣and␣try␣again.");
    end;
  succumb;
  end;

100.   Users occasionally want to interrupt T$_{E}$X while it's running. If the Pascal runtime system allows this, one can implement a routine that sets the global variable *interrupt* to some nonzero value when such an interrupt is signalled. Otherwise there is probably at least a way to make *interrupt* nonzero using the Pascal debugger.

> **define** *check_interrupt* ≡
> > **begin if** *interrupt* ≠ 0 **then** *pause_for_instructions*;
> > **end**

⟨ Global variables 13 ⟩ +≡
interrupt: *integer*;   { should T$_{E}$X pause for instructions? }
OK_to_interrupt: *boolean*;   { should interrupts be observed? }

101.   ⟨Set initial values of key variables 23⟩ +≡
  interrupt ← 0; *OK_to_interrupt* ← *true*;

102.   When an interrupt has been detected, the program goes into its highest interaction level and lets the user have nearly the full flexibility of the *error* routine. TEX checks for interrupts only at times when it is safe to do this.

procedure *pause_for_instructions*;
  begin if *OK_to_interrupt* **then**
    begin *interaction* ← *error_stop_mode*;
    if (*selector* = *log_only*) ∨ (*selector* = *no_print*) **then** *incr*(*selector*);
    print_err("Interruption"); *help3*("You␣rang?")
    ("Try␣to␣insert␣an␣instruction␣for␣me␣(e.g.,␣`I\showlists´),")
    ("unless␣you␣just␣want␣to␣quit␣by␣typing␣`X´."); *deletions_allowed* ← *false*; *error*;
    deletions_allowed ← *true*; *interrupt* ← 0;
    end;
  end;

103.   Arithmetic with scaled dimensions.   The principal computations performed by TEX are done entirely in terms of integers less than 2^{31} in magnitude; and divisions are done only when both dividend and divisor are nonnegative. Thus, the arithmetic specified in this program can be carried out in exactly the same way on a wide variety of computers, including some small ones. Why? Because the arithmetic calculations need to be spelled out precisely in order to guarantee that TEX will produce identical output on different machines. If some quantities were rounded differently in different implementations, we would find that line breaks and even page breaks might occur in different places. Hence the arithmetic of TEX has been designed with care, and systems that claim to be implementations of TEX82 should follow precisely the calculations as they appear in the present program.

(Actually there are three places where TEX uses **div** with a possibly negative numerator. These are harmless; see **div** in the index. Also if the user sets the \time or the \year to a negative value, some diagnostic information will involve negative-numerator division. The same remarks apply for **mod** as well as for **div**.)

104.   Here is a routine that calculates half of an integer, using an unambiguous convention with respect to signed odd numbers.

function $half(x : integer)$: $integer$;
  begin if $odd(x)$ **then** $half \leftarrow (x + 1)$ **div** 2
  else $half \leftarrow x$ **div** 2;
  end;

105.   Fixed-point arithmetic is done on *scaled integers* that are multiples of 2^{-16}. In other words, a binary point is assumed to be sixteen bit positions from the right end of a binary computer word.

  define $unity \equiv \text{´}200000$ { 2^{16}, represents 1.00000 }
  define $two \equiv \text{´}400000$ { 2^{17}, represents 2.00000 }

⟨ Types in the outer block 18 ⟩ +≡
  $scaled = integer$;   { this type is used for scaled integers }
  $nonnegative\_integer = 0 \mathinner{\ldotp\ldotp} \text{´}17777777777$;   { $0 \leq x < 2^{31}$ }
  $small\_number = 0 \mathinner{\ldotp\ldotp} hyphenatable\_length\_limit$;   { this type is self-explanatory }

106.   The following function is used to create a scaled integer from a given decimal fraction $(.d_0d_1 \ldots d_{k-1})$, where $0 \leq k \leq 17$. The digit d_i is given in $dig[i]$, and the calculation produces a correctly rounded result.

function $round\_decimals(k : small\_number)$: $scaled$;   { converts a decimal fraction }
  var a: $integer$;   { the accumulator }
  begin $a \leftarrow 0$;
  while $k > 0$ **do**
    begin $decr(k)$; $a \leftarrow (a + dig[k] * two)$ **div** 10;
    end;
  $round\_decimals \leftarrow (a + 1)$ **div** 2;
  end;

107.   Conversely, here is a procedure analogous to *print_int*. If the output of this procedure is subsequently read by TEX and converted by the *round_decimals* routine above, it turns out that the original value will be reproduced exactly; the "simplest" such decimal number is output, but there is always at least one digit following the decimal point.

The invariant relation in the **repeat** loop is that a sequence of decimal digits yet to be printed will yield the original number if and only if they form a fraction f in the range $s - \delta \leq 10 \cdot 2^{16} f < s$. We can stop if and only if $f = 0$ satisfies this condition; the loop will terminate before s can possibly become zero.

procedure *print_scaled*(*s* : *scaled*);   { prints scaled real, rounded to five digits }
    var *delta*: *scaled*;   { amount of allowable inaccuracy }
    begin if $s < 0$ **then**
        begin *print_char*("−"); *negate*(*s*);   { print the sign, if negative }
        end;
    print_int(*s* **div** *unity*);   { print the integer part }
    print_char("."); $s \leftarrow 10 * (s \bmod unity) + 5$; $delta \leftarrow 10$;
    repeat if *delta* > *unity* **then** $s \leftarrow s + ´100000 - 50000$;   { round the last digit }
        print_char("0" + (*s* **div** *unity*)); $s \leftarrow 10 * (s \bmod unity)$; $delta \leftarrow delta * 10$;
    until $s \leq delta$;
    end;

108.   Physical sizes that a TEX user specifies for portions of documents are represented internally as scaled points. Thus, if we define an 'sp' (scaled point) as a unit equal to 2^{-16} printer's points, every dimension inside of TEX is an integer number of sp. There are exactly 4,736,286.72 sp per inch. Users are not allowed to specify dimensions larger than $2^{30} - 1$ sp, which is a distance of about 18.892 feet (5.7583 meters); two such quantities can be added without overflow on a 32-bit computer.

The present implementation of TEX does not check for overflow when dimensions are added or subtracted. This could be done by inserting a few dozen tests of the form '**if** $x \geq ´10000000000$ **then** *report_overflow*', but the chance of overflow is so remote that such tests do not seem worthwhile.

TEX needs to do only a few arithmetic operations on scaled quantities, other than addition and subtraction, and the following subroutines do most of the work. A single computation might use several subroutine calls, and it is desirable to avoid producing multiple error messages in case of arithmetic overflow; so the routines set the global variable *arith_error* to *true* instead of reporting errors directly to the user. Another global variable, *remainder*, holds the remainder after a division.

⟨ Global variables 13 ⟩ +≡
arith_error: *boolean*;   { has arithmetic overflow occurred recently? }
remainder: *scaled*;   { amount subtracted to get an exact division }

109.   The first arithmetical subroutine we need computes $nx + y$, where x and y are *scaled* and n is an integer. We will also use it to multiply integers.

    define *nx_plus_y*(#) ≡ *mult_and_add*(#, ´7777777777)
    define *mult_integers*(#) ≡ *mult_and_add*(#, 0, ´17777777777)

function *mult_and_add*(*n* : *integer*; *x*, *y*, *max_answer* : *scaled*): *scaled*;
    begin if $n < 0$ **then**
        begin *negate*(*x*); *negate*(*n*);
        end;
    if $n = 0$ **then** *mult_and_add* ← *y*
    else if ((*x* ≤ (*max_answer* − *y*) **div** *n*) ∧ (−*x* ≤ (*max_answer* + *y*) **div** *n*)) **then** *mult_and_add* ← *n* ∗ *x* + *y*
        else begin *arith_error* ← *true*; *mult_and_add* ← 0;
            end;
    end;

110.   We also need to divide scaled dimensions by integers.

function $x\_over\_n(x: scaled; n: integer): scaled;$
 var $negative: boolean;$ { should $remainder$ be negated? }
 begin $negative \leftarrow false;$
 if $n = 0$ **then**
  begin $arith\_error \leftarrow true; x\_over\_n \leftarrow 0; remainder \leftarrow x;$
  end
 else begin if $n < 0$ **then**
   begin $negate(x); negate(n); negative \leftarrow true;$
   end;
  if $x \geq 0$ **then**
   begin $x\_over\_n \leftarrow x$ **div** $n; remainder \leftarrow x$ **mod** $n;$
   end
  else begin $x\_over\_n \leftarrow -((-x)$ **div** $n); remainder \leftarrow -((-x)$ **mod** $n);$
   end;
  end;
 if $negative$ **then** $negate(remainder);$
 end;

111.   Then comes the multiplication of a scaled number by a fraction n/d, where n and d are nonnegative integers $\leq 2^{16}$ and d is positive. It would be too dangerous to multiply by n and then divide by d, in separate operations, since overflow might well occur; and it would be too inaccurate to divide by d and then multiply by n. Hence this subroutine simulates 1.5-precision arithmetic.

function $xn\_over\_d(x: scaled; n, d: integer): scaled;$
 var $positive: boolean;$ { was $x \geq 0$? }
  $t, u, v: nonnegative\_integer;$ { intermediate quantities }
 begin if $x \geq 0$ **then** $positive \leftarrow true$
 else begin $negate(x); positive \leftarrow false;$
  end;
 $t \leftarrow (x$ **mod** $´100000) * n; u \leftarrow (x$ **div** $´100000) * n + (t$ **div** $´100000);$
 $v \leftarrow (u$ **mod** $d) * ´100000 + (t$ **mod** $´100000);$
 if u **div** $d \geq ´100000$ **then** $arith\_error \leftarrow true$
 else $u \leftarrow ´100000 * (u$ **div** $d) + (v$ **div** $d);$
 if $positive$ **then**
  begin $xn\_over\_d \leftarrow u; remainder \leftarrow v$ **mod** $d;$
  end
 else begin $xn\_over\_d \leftarrow -u; remainder \leftarrow -(v$ **mod** $d);$
  end;
 end;

112.   The next subroutine is used to compute the "badness" of glue, when a total t is supposed to be made from amounts that sum to s. According to *The T_EXbook*, the badness of this situation is $100(t/s)^3$; however, badness is simply a heuristic, so we need not squeeze out the last drop of accuracy when computing it. All we really want is an approximation that has similar properties.

The actual method used to compute the badness is easier to read from the program than to describe in words. It produces an integer value that is a reasonably close approximation to $100(t/s)^3$, and all implementations of T_EX should use precisely this method. Any badness of 2^{13} or more is treated as infinitely bad, and represented by 10000.

It is not difficult to prove that

$$badness(t + 1, s) \geq badness(t, s) \geq badness(t, s + 1).$$

The badness function defined here is capable of computing at most 1095 distinct values, but that is plenty.

define $inf\_bad = 10000$ { infinitely bad value }

function $badness(t, s : scaled)$: $halfword$;   { compute badness, given $t \geq 0$ }
  var r: $integer$;   { approximation to $\alpha t/s$, where $\alpha^3 \approx 100 \cdot 2^{18}$ }
  begin if $t = 0$ **then** $badness \leftarrow 0$
  else if $s \leq 0$ **then** $badness \leftarrow inf\_bad$
    else begin if $t \leq 7230584$ **then** $r \leftarrow (t * 297)$ **div** s { $297^3 = 99.94 \times 2^{18}$ }
      else if $s \geq 1663497$ **then** $r \leftarrow t$ **div** $(s$ **div** $297)$
        else $r \leftarrow t$;
      if $r > 1290$ **then** $badness \leftarrow inf\_bad$ { $1290^3 < 2^{31} < 1291^3$ }
      else $badness \leftarrow (r * r * r + \text{´}400000)$ **div** $\text{´}1000000$;
      end;   { that was $r^3/2^{18}$, rounded to the nearest integer }
  end;

113.   When T_EX "packages" a list into a box, it needs to calculate the proportionality ratio by which the glue inside the box should stretch or shrink. This calculation does not affect T_EX's decision making, so the precise details of rounding, etc., in the glue calculation are not of critical importance for the consistency of results on different computers.

We shall use the type *glue_ratio* for such proportionality ratios. A glue ratio should take the same amount of memory as an *integer* (usually 32 bits) if it is to blend smoothly with T_EX's other data structures. Thus *glue_ratio* should be equivalent to *short_real* in some implementations of Pascal. Alternatively, it is possible to deal with glue ratios using nothing but fixed-point arithmetic; see *TUGboat* **3**,1 (March 1982), 10–27. (But the routines cited there must be modified to allow negative glue ratios.)

define $set\_glue\_ratio\_zero(\#) \equiv \# \leftarrow 0.0$ { store the representation of zero ratio }
define $set\_glue\_ratio\_one(\#) \equiv \# \leftarrow 1.0$ { store the representation of unit ratio }
define $float(\#) \equiv \#$ { convert from *glue_ratio* to type *real* }
define $unfloat(\#) \equiv \#$ { convert from *real* to type *glue_ratio* }
define $float\_constant(\#) \equiv \#.0$ { convert *integer* constant to *real* }

⟨ Types in the outer block 18 ⟩ +≡
  $glue\_ratio = real$;   { one-word representation of a glue expansion factor }

114. Random numbers.

This section is (almost) straight from MetaPost. I had to change the types (use *integer* instead of *fraction*), but that should not have any influence on the actual calculations (the original comments refer to quantities like *fraction_four* (2^{30}), and that is the same as the numeric representation of *maxdimen*).

I've copied the low-level variables and routines that are needed, but only those (e.g. *m_log*), not the accompanying ones like *m_exp*. Most of the following low-level numeric routines are only needed within the calculation of *norm_rand*. I've been forced to rename *make_fraction* to *make_frac* because TeX already has a routine by that name with a wholly different function (it creates a *fraction_noad* for math typesetting) – Taco

And now let's complete our collection of numeric utility routines by considering random number generation. METAPOST generates pseudo-random numbers with the additive scheme recommended in Section 3.6 of *The Art of Computer Programming*; however, the results are random fractions between 0 and *fraction_one* − 1, inclusive.

There's an auxiliary array *randoms* that contains 55 pseudo-random fractions. Using the recurrence $x_n = (x_{n-55} - x_{n-31}) \bmod 2^{28}$, we generate batches of 55 new x_n's at a time by calling *new_randoms*. The global variable *j_random* tells which element has most recently been consumed.

⟨ Global variables 13 ⟩ +≡
randoms: **array** [0 . . 54] **of** *integer*;   { the last 55 random values generated }
j_random: 0 . . 54;   { the number of unused *randoms* }
random_seed: *scaled*;   { the default random seed }

115. A small bit of metafont is needed.

define *fraction_half* ≡ ´1000000000   { 2^{27}, represents 0.50000000 }
define *fraction_one* ≡ ´2000000000   { 2^{28}, represents 1.00000000 }
define *fraction_four* ≡ ´10000000000   { 2^{30}, represents 4.00000000 }
define *el_gordo* ≡ ´17777777777   { $2^{31} - 1$, the largest value that METAPOST likes }
define *halfp*(#) ≡ (#) **div** 2
define *double*(#) ≡ # ← # + #   { multiply a variable by two }

116.   The *make_frac* routine produces the *fraction* equivalent of p/q, given integers p and q; it computes the integer $f = \lfloor 2^{28}p/q + \frac{1}{2} \rfloor$, when p and q are positive. If p and q are both of the same scaled type t, the "type relation" *make_frac*$(t, t) = fraction$ is valid; and it's also possible to use the subroutine "backwards," using the relation *make_frac*$(t, fraction) = t$ between scaled types.

If the result would have magnitude 2^{31} or more, *make_frac* sets *arith_error* $\leftarrow$ *true*. Most of METAPOST's internal computations have been designed to avoid this sort of error.

If this subroutine were programmed in assembly language on a typical machine, we could simply compute $(2^{28} * p)$ **div** q, since a double-precision product can often be input to a fixed-point division instruction. But when we are restricted to Pascal arithmetic it is necessary either to resort to multiple-precision maneuvering or to use a simple but slow iteration. The multiple-precision technique would be about three times faster than the code adopted here, but it would be comparatively long and tricky, involving about sixteen additional multiplications and divisions.

This operation is part of METAPOST's "inner loop"; indeed, it will consume nearly 10% of the running time (exclusive of input and output) if the code below is left unchanged. A machine-dependent recoding will therefore make METAPOST run faster. The present implementation is highly portable, but slow; it avoids multiplication and division except in the initial stage. System wizards should be careful to replace it with a routine that is guaranteed to produce identical results in all cases.

As noted below, a few more routines should also be replaced by machine-dependent code, for efficiency. But when a procedure is not part of the "inner loop," such changes aren't advisable; simplicity and robustness are preferable to trickery, unless the cost is too high.

```
function make_frac(p, q : integer): integer;
    var f: integer;   { the fraction bits, with a leading 1 bit }
        n: integer;   { the integer part of |p/q| }
        negative: boolean;   { should the result be negated? }
        be_careful: integer;   { disables certain compiler optimizations }
    begin if p ≥ 0 then negative ← false
    else begin negate(p); negative ← true;
        end;
    if q ≤ 0 then
        begin debug if q = 0 then confusion("/"); gubed
        negate(q); negative ← ¬negative;
        end;
    n ← p div q;  p ← p mod q;
    if n ≥ 8 then
        begin arith_error ← true;
        if negative then make_frac ← −el_gordo else make_frac ← el_gordo;
        end
    else begin n ← (n − 1) ∗ fraction_one; ⟨Compute f = ⌊2²⁸(1 + p/q) + ½⌋ 117⟩;
        if negative then make_frac ← −(f + n) else make_frac ← f + n;
        end;
    end;
```

117. The **repeat** loop here preserves the following invariant relations between f, p, and q: (i) $0 \le p < q$; (ii) $fq + p = 2^k(q + p_0)$, where k is an integer and p_0 is the original value of p.

Notice that the computation specifies $(p-q)+p$ instead of $(p+p)-q$, because the latter could overflow. Let us hope that optimizing compilers do not miss this point; a special variable *be_careful* is used to emphasize the necessary order of computation. Optimizing compilers should keep *be_careful* in a register, not store it in memory.

⟨ Compute $f = \lfloor 2^{28}(1 + p/q) + \frac{1}{2} \rfloor$ 117 ⟩ ≡
  $f \leftarrow 1$;
  repeat *be_careful* $\leftarrow p - q$; $p \leftarrow$ *be_careful* $+ p$;
    if $p \ge 0$ **then** $f \leftarrow f + f + 1$
    else begin *double*(f); $p \leftarrow p + q$;
      end;
  until $f \ge$ *fraction_one*;
  be_careful $\leftarrow p - q$;
  if *be_careful* $+ p \ge 0$ **then** *incr*(f)
This code is used in section 116.

118.

function *take_frac*$(q : integer; f : integer): integer$;
  var p: *integer*;   { the fraction so far }
    negative: *boolean*;   { should the result be negated? }
    n: *integer*;   { additional multiple of q }
    be_careful: *integer*;   { disables certain compiler optimizations }
  begin ⟨ Reduce to the case that $f \ge 0$ and $q > 0$ 119 ⟩;
  if $f <$ *fraction_one* **then** $n \leftarrow 0$

      if $q > r$ **then** $return\_sign(1)$ **else** $return\_sign(-1)$;
    $q \leftarrow a \textbf{ mod } d$; $r \leftarrow c \textbf{ mod } b$;
    if $r = 0$ **then**
      if $q = 0$ **then** $return\_sign(0)$ **else** $return\_sign(1)$;
    if $q = 0$ **then** $return\_sign(-1)$;
    $a \leftarrow b$; $b \leftarrow q$; $c \leftarrow d$; $d \leftarrow r$;
    end;   { now $a > d > 0$ and $c > b > 0$ }
$exit$: **end**;

127.   ⟨Reduce to the case that $a, c \geq 0$, $b, d > 0$ 127⟩ ≡
  if $a < 0$ **then**
    begin $negate(a)$; $negate(b)$;
    end;
  if $c < 0$ **then**
    begin $negate(c)$; $negate(d)$;
    end;
  if $d \leq 0$ **then**
    begin if $b \geq 0$ **then**
      if $((a = 0) \vee (b = 0)) \wedge ((c = 0) \vee (d = 0))$ **then** $return\_sign(0)$
      else $return\_sign(1)$;
    if $d = 0$ **then**
      if $a = 0$ **then** $return\_sign(0)$ **else** $return\_sign(-1)$;
    $q \leftarrow a$; $a \leftarrow c$; $c \leftarrow q$; $q \leftarrow -b$; $b \leftarrow -d$; $d \leftarrow q$;
    end
  else if $b \leq 0$ **then**
      begin if $b < 0$ **then**
        if $a > 0$ **then** $return\_sign(-1)$;
      if $c = 0$ **then** $return\_sign(0)$
      else $return\_sign(-1)$;
      end

This code is used in section 126.

128.   To consume a random integer, the program below will say '$next\_random$' and then it will fetch $randoms[j\_random]$.

  define $next\_random \equiv$
        if $j\_random = 0$ **then** $new\_randoms$
        else $decr(j\_random)$

procedure $new\_randoms$;
  var k: $0 \dots 54$;   {index into $randoms$}
    x: $integer$;   {accumulator}
  begin for $k \leftarrow 0$ **to** 23 **do**
    begin $x \leftarrow randoms[k] - randoms[k + 31]$;
    if $x < 0$ **then** $x \leftarrow x + fraction\_one$;
    $randoms[k] \leftarrow x$;
    end;
  for $k \leftarrow 24$ **to** 54 **do**
    begin $x \leftarrow randoms[k] - randoms[k - 24]$;
    if $x < 0$ **then** $x \leftarrow x + fraction\_one$;
    $randoms[k] \leftarrow x$;
    end;
  $j\_random \leftarrow 54$;
  end;

129.   To initialize the *randoms* table, we call the following routine.

procedure *init_randoms*(*seed* : *integer*);
  var *j, jj, k*: *integer*;   { more or less random integers }
    i: 0 . . 54;   { index into *randoms* }
  begin *j* ← *abs*(*seed*);
  while *j* ≥ *fraction_one* **do** *j* ← *halfp*(*j*);
  k ← 1;
  for *i* ← 0 **to** 54 **do**
    begin *jj* ← *k*; *k* ← *j* − *k*; *j* ← *jj*;
    if *k* < 0 **then** *k* ← *k* + *fraction_one*;
    randoms[(*i* ∗ 21) **mod** 55] ← *j*;
    end;
  new_randoms; *new_randoms*; *new_randoms*;   { "warm up" the array }
  end;

130.   To produce a uniform random number in the range $0 \le u < x$ or $0 \ge u > x$ or $0 = u = x$, given a *scaled* value x, we proceed as shown here.

Note that the call of *take_frac* will produce the values 0 and x with about half the probability that it will produce any other particular values between 0 and x, because it rounds its answers.

function *unif_rand*(*x* : *integer*): *integer*;
  var *y*: *integer*;   { trial value }
  begin *next_random*; *y* ← *take_frac*(*abs*(*x*), *randoms*[*j_random*]);
  if *y* = *abs*(*x*) **then** *unif_rand* ← 0
  else if *x* > 0 **then** *unif_rand* ← *y*
    else *unif_rand* ← −*y*;
  end;

131.   Finally, a normal deviate with mean zero and unit standard deviation can readily be obtained with the ratio method (Algorithm 3.4.1R in *The Art of Computer Programming*).

function *norm_rand*: *integer*;
  var *x, u, l*: *integer*;   { what the book would call $2^{16}X$, $2^{28}U$, and $-2^{24} \ln U$ }
  begin repeat repeat *next_random*; *x* ← *take_frac*(112429, *randoms*[*j_random*] − *fraction_half*);
        { $2^{16}\sqrt{8/e} \approx 112428.82793$ }
    next_random; *u* ← *randoms*[*j_random*];
  until *abs*(*x*) < *u*;
  x ← *make_frac*(*x, u*); *l* ← 139548960 − *m_log*(*u*);   { $2^{24} \cdot 12 \ln 2 \approx 139548959.6165$ }
  until *ab_vs_cd*(1024, *l, x, x*) ≥ 0;
  norm_rand ← *x*;
  end;

132.   Packed data.   In order to make efficient use of storage space, T_EX bases its major data structures on a *memory_word*, which contains either a (signed) integer, possibly scaled, or a (signed) *glue_ratio*, or a small number of fields that are one half or one quarter of the size used for storing integers.

If x is a variable of type *memory_word*, it contains up to four fields that can be referred to as follows:

$$
\begin{array}{ll}
x.int & (\text{an } integer)\\
x.sc & (\text{a } scaled \text{ integer})\\
x.gr & (\text{a } glue\_ratio)\\
x.hh.lh,\ x.hh.rh & (\text{two halfword fields})\\
x.hh.b0,\ x.hh.b1,\ x.hh.rh & (\text{two quarterword fields, one halfword field})\\
x.qqqq.b0,\ x.qqqq.b1,\ x.qqqq.b2,\ x.qqqq.b3 & (\text{four quarterword fields})
\end{array}
$$

This is somewhat cumbersome to write, and not very readable either, but macros will be used to make the notation shorter and more transparent. The Pascal code below gives a formal definition of *memory_word* and its subsidiary types, using packed variant records. T_EX makes no assumptions about the relative positions of the fields within a word.

Since we are assuming 32-bit integers, a halfword must contain at least 16 bits, and a quarterword must contain at least 8 bits. But it doesn't hurt to have more bits; for example, with enough 36-bit words you might be able to have *mem_max* as large as 262142, which is eight times as much memory as anybody had during the first four years of T_EX's existence.

N.B.: Valuable memory space will be dreadfully wasted unless T_EX is compiled by a Pascal that packs all of the *memory_word* variants into the space of a single integer. This means, for example, that *glue_ratio* words should be *short_real* instead of *real* on some computers. Some Pascal compilers will pack an integer whose subrange is '0 . . 255' into an eight-bit field, but others insist on allocating space for an additional sign bit; on such systems you can get 256 values into a quarterword only if the subrange is '−128 . . 127'.

The present implementation tries to accommodate as many variations as possible, so it makes few assumptions. If integers having the subrange '*min_quarterword* . . *max_quarterword*' can be packed into a quarterword, and if integers having the subrange '*min_halfword* . . *max_halfword*' can be packed into a halfword, everything should work satisfactorily.

It is usually most efficient to have *min_quarterword* = *min_halfword* = 0, so one should try to achieve this unless it causes a severe problem. The values defined here are recommended for most 32-bit computers.

define *min_quarterword* = 0   { smallest allowable value in a *quarterword* }
define *max_quarterword* = ″FFFF   { largest allowable value in a *quarterword* }
define *min_halfword* ≡ −″FFFFFFF   { smallest allowable value in a *halfword* }
define *max_halfword* ≡ ″3FFFFFFF   { largest allowable value in a *halfword* }

133.   Here are the inequalities that the quarterword and halfword values must satisfy (or rather, the inequalities that they mustn't satisfy):

⟨ Check the "constant" values for consistency 14 ⟩ +≡
   init if (*mem_min* ≠ *mem_bot*) ∨ (*mem_max* ≠ *mem_top*) **then** *bad* ← 10;
   tini
   if (*mem_min* > *mem_bot*) ∨ (*mem_max* < *mem_top*) **then** *bad* ← 10;
   if (*min_quarterword* > 0) ∨ (*max_quarterword* < ″7FFF) **then** *bad* ← 11;
   if (*min_halfword* > 0) ∨ (*max_halfword* < ″3FFFFFFF) **then** *bad* ← 12;
   if (*min_quarterword* < *min_halfword*) ∨ (*max_quarterword* > *max_halfword*) **then** *bad* ← 13;
   if (*mem_min* < *min_halfword*) ∨ (*mem_max* ≥ *max_halfword*) ∨
         (*mem_bot* − *mem_min* > *max_halfword* + 1) **then** *bad* ← 14;
   if (*font_base* < *min_quarterword*) ∨ (*font_max* > *max_quarterword*) **then** *bad* ← 15;
   if *font_max* > *font_base* + 256 **then** *bad* ← 16;
   if (*save_size* > *max_halfword*) ∨ (*max_strings* > *max_halfword*) **then** *bad* ← 17;
   if *buf_size* > *max_halfword* **then** *bad* ← 18;
   if *max_quarterword* − *min_quarterword* < ″FFFF **then** *bad* ← 19;

134.   The operation of adding or subtracting *min_quarterword* occurs quite frequently in TEX, so it is convenient to abbreviate this operation by using the macros *qi* and *qo* for input and output to and from quarterword format.

The inner loop of TEX will run faster with respect to compilers that don't optimize expressions like '$x + 0$' and '$x - 0$', if these macros are simplified in the obvious way when *min_quarterword* = 0.

> **define** *qi*(#) ≡ # + *min_quarterword*   { to put an *eight_bits* item into a quarterword }
> **define** *qo*(#) ≡ # − *min_quarterword*   { to take an *eight_bits* item out of a quarterword }
> **define** *hi*(#) ≡ # + *min_halfword*   { to put a sixteen-bit item into a halfword }
> **define** *ho*(#) ≡ # − *min_halfword*   { to take a sixteen-bit item from a halfword }

135.   The reader should study the following definitions closely:

> **define** *sc* ≡ *int*   { *scaled* data is equivalent to *integer* }

⟨ Types in the outer block 18 ⟩ +≡
  quarterword = *min_quarterword* .. *max_quarterword*;   { 1/4 of a word }
  halfword = *min_halfword* .. *max_halfword*;   { 1/2 of a word }
  two_choices = 1 .. 2;   { used when there are two variants in a record }
  four_choices = 1 .. 4;   { used when there are four variants in a record }
  two_halves = **packed record** *rh*: *halfword*;
    case *two_choices* **of**
    1: (*lh* : *halfword*);
    2: (*b0* : *quarterword*; *b1* : *quarterword*);
    end;
  four_quarters = **packed record** *b0*: *quarterword*;
    b1: *quarterword*;
    b2: *quarterword*;
    b3: *quarterword*;
    end;
  memory_word = **record**
    case *four_choices* **of**
    1: (*int* : *integer*);
    2: (*gr* : *glue_ratio*);
    3: (*hh* : *two_halves*);
    4: (*qqqq* : *four_quarters*);
    end;
  word_file = *gzFile*;

136.   When debugging, we may want to print a *memory_word* without knowing what type it is; so we print it in all modes.

> **debug procedure** *print_word*(*w* : *memory_word*);   { prints *w* in all ways }
> **begin** *print_int*(*w.int*); *print_char*("␣");
> *print_scaled*(*w.sc*); *print_char*("␣");
> *print_scaled*(*round*(*unity* ∗ *float*(*w.gr*))); *print_ln*;
> *print_int*(*w.hh.lh*); *print_char*("="); *print_int*(*w.hh.b0*); *print_char*(":"); *print_int*(*w.hh.b1*);
> *print_char*(";"); *print_int*(*w.hh.rh*); *print_char*("␣");
> *print_int*(*w.qqqq.b0*); *print_char*(":"); *print_int*(*w.qqqq.b1*); *print_char*(":"); *print_int*(*w.qqqq.b2*);
> *print_char*(":"); *print_int*(*w.qqqq.b3*);
> **end**;
> **gubed**

137. Dynamic memory allocation.   The T$_{\mathrm{E}}$X system does nearly all of its own memory allocation, so that it can readily be transported into environments that do not have automatic facilities for strings, garbage collection, etc., and so that it can be in control of what error messages the user receives. The dynamic storage requirements of T$_{\mathrm{E}}$X are handled by providing a large array *mem* in which consecutive blocks of words are used as nodes by the T$_{\mathrm{E}}$X routines.

Pointer variables are indices into this array, or into another array called *eqtb* that will be explained later. A pointer variable might also be a special flag that lies outside the bounds of *mem*, so we allow pointers to assume any *halfword* value. The minimum halfword value represents a null pointer. T$_{\mathrm{E}}$X does not assume that *mem*[*null*] exists.

define *pointer* $\equiv$ *halfword*   { a flag or a location in *mem* or *eqtb* }
define *null* $\equiv$ *min_halfword*   { the null pointer }

⟨ Global variables 13 ⟩ +≡
temp_ptr: *pointer*;   { a pointer variable for occasional emergency use }

138.   The *mem* array is divided into two regions that are allocated separately, but the dividing line between these two regions is not fixed; they grow together until finding their "natural" size in a particular job. Locations less than or equal to *lo_mem_max* are used for storing variable-length records consisting of two or more words each. This region is maintained using an algorithm similar to the one described in exercise 2.5–19 of *The Art of Computer Programming*. However, no size field appears in the allocated nodes; the program is responsible for knowing the relevant size when a node is freed. Locations greater than or equal to *hi_mem_min* are used for storing one-word records; a conventional AVAIL stack is used for allocation in this region.

Locations of *mem* between *mem_bot* and *mem_top* may be dumped as part of preloaded format files, by the INITEX preprocessor. Production versions of T$_{\mathrm{E}}$X may extend the memory at both ends in order to provide more space; locations between *mem_min* and *mem_bot* are always used for variable-size nodes, and locations between *mem_top* and *mem_max* are always used for single-word nodes.

The key pointers that govern *mem* allocation have a prescribed order:

$$null \le mem\_min \le mem\_bot < lo\_mem\_max < hi\_mem\_min < mem\_top \le mem\_end \le mem\_max.$$

Empirical tests show that the present implementation of T$_{\mathrm{E}}$X tends to spend about 9% of its running time allocating nodes, and about 6% deallocating them after their use.

⟨ Global variables 13 ⟩ +≡
mem: **array** [*mem_min* .. *mem_max*] **of** *memory_word*;   { the big dynamic storage area }
lo_mem_max: *pointer*;   { the largest location of variable-size memory in use }
hi_mem_min: *pointer*;   { the smallest location of one-word memory in use }

139.   In order to study the memory requirements of particular applications, it is possible to prepare a version of T$_{\mathrm{E}}$X that keeps track of current and maximum memory usage. When code between the delimiters **stat** ... **tats** is not "commented out," T$_{\mathrm{E}}$X will run a bit slower but it will report these statistics when *tracing_stats* is sufficiently large.

⟨ Global variables 13 ⟩ +≡
var_used, *dyn_used*: *integer*;   { how much memory is in use }

140.   Let's consider the one-word memory region first, since it's the simplest. The pointer variable *mem_end* holds the highest-numbered location of *mem* that has ever been used. The free locations of *mem* that occur between *hi_mem_min* and *mem_end*, inclusive, are of type *two_halves*, and we write *info*(*p*) and *link*(*p*) for the *lh* and *rh* fields of *mem*[*p*] when it is of this type. The single-word free locations form a linked list

$$avail,\ link(avail),\ link(link(avail)),\ \ldots$$

terminated by *null*.

   define *link*(#) ≡ *mem*[#].*hh*.*rh*   { the *link* field of a memory word }
   define *info*(#) ≡ *mem*[#].*hh*.*lh*   { the *info* field of a memory word }

⟨ Global variables 13 ⟩ +≡
avail: *pointer*;   { head of the list of available one-word nodes }
mem_end: *pointer*;   { the last one-word node used in *mem* }

141.   If memory is exhausted, it might mean that the user has forgotten a right brace. We will define some procedures later that try to help pinpoint the trouble.

   ⟨ Declare the procedure called *show_token_list* 322 ⟩
   ⟨ Declare the procedure called *runaway* 336 ⟩

142.   The function *get_avail* returns a pointer to a new one-word node whose *link* field is null. However, TEX will halt if there is no more room left.

   If the available-space list is empty, i.e., if *avail* = *null*, we try first to increase *mem_end*. If that cannot be done, i.e., if *mem_end* = *mem_max*, we try to decrease *hi_mem_min*. If that cannot be done, i.e., if *hi_mem_min* = *lo_mem_max* + 1, we have to quit.

function *get_avail*: *pointer*;   { single-word node allocation }
   var *p*: *pointer*;   { the new node being got }
   begin *p* ← *avail*;   { get top location in the *avail* stack }
   if *p* ≠ *null* **then** *avail* ← *link*(*avail*)   { and pop it off }
   else if *mem_end* < *mem_max* **then**   { or go into virgin territory }
         begin *incr*(*mem_end*); *p* ← *mem_end*;
         end
      else begin *decr*(*hi_mem_min*); *p* ← *hi_mem_min*;
         if *hi_mem_min* ≤ *lo_mem_max* **then**
            begin *runaway*;   { if memory is exhausted, display possible runaway text }
            overflow("main␣memory␣size", *mem_max* + 1 − *mem_min*);   { quit; all one-word nodes are busy }
            end;
         end;
   link(*p*) ← *null*;   { provide an oft-desired initialization of the new node }
   stat *incr*(*dyn_used*); **tats**   { maintain statistics }
   get_avail ← *p*;
   end;

143.   Conversely, a one-word node is recycled by calling *free_avail*. This routine is part of TEX's "inner loop," so we want it to be fast.

   define *free_avail*(#) ≡   { single-word node liberation }
         begin *link*(#) ← *avail*; *avail* ← #;
         stat *decr*(*dyn_used*); **tats**
         end

144.   There's also a *fast_get_avail* routine, which saves the procedure-call overhead at the expense of extra programming. This routine is used in the places that would otherwise account for the most calls of *get_avail*.

> **define** *fast_get_avail*(#) ≡
>   **begin** # ← *avail*;   { avoid *get_avail* if possible, to save time }
>   **if** # = *null* **then** # ← *get_avail*
>   **else begin** *avail* ← *link*(#); *link*(#) ← *null*;
>   **stat** *incr*(*dyn_used*); **tats**
>   **end**;
>   **end**

145.   The procedure *flush_list*(p) frees an entire linked list of one-word nodes that starts at position p.

procedure *flush_list*(p : *pointer*);   { makes list of single-word nodes available }
  var q, r: *pointer*;   { list traversers }
  begin if p ≠ *null* **then**
    begin r ← p;
    repeat q ← r; r ← *link*(r);
       stat *decr*(*dyn_used*); **tats**
    until r = *null*;   { now q is the last node on the list }
    link(q) ← *avail*; *avail* ← p;
    end;
  end;

146.   The available-space list that keeps track of the variable-size portion of *mem* is a nonempty, doubly-linked circular list of empty nodes, pointed to by the roving pointer *rover*.

  Each empty node has size 2 or more; the first word contains the special value *max_halfword* in its *link* field and the size in its *info* field; the second word contains the two pointers for double linking.

  Each nonempty node also has size 2 or more. Its first word is of type *two_halves*, and its *link* field is never equal to *max_halfword*. Otherwise there is complete flexibility with respect to the contents of its other fields and its other words.

  (We require *mem_max* < *max_halfword* because terrible things can happen when *max_halfword* appears in the *link* field of a nonempty node.)

> **define** *empty_flag* ≡ *max_halfword*   { the *link* of an empty variable-size node }
> **define** *is_empty*(#) ≡ (*link*(#) = *empty_flag*)   { tests for empty node }
> **define** *node_size* ≡ *info*   { the size field in empty variable-size nodes }
> **define** *llink*(#) ≡ *info*(# + 1)   { left link in doubly-linked list of empty nodes }
> **define** *rlink*(#) ≡ *link*(# + 1)   { right link in doubly-linked list of empty nodes }

⟨ Global variables 13 ⟩ +≡
rover: *pointer*;   { points to some node in the list of empties }

147.   A call to *get_node* with argument *s* returns a pointer to a new node of size *s*, which must be 2 or more. The *link* field of the first word of this new node is set to null. An overflow stop occurs if no suitable space exists.

   If *get_node* is called with $s = 2^{30}$, it simply merges adjacent free areas and returns the value *max_halfword*.

function *get_node*(*s* : *integer*): *pointer*;   { variable-size node allocation }
  label *found*, *exit*, *restart*;
  var *p*: *pointer*;   { the node currently under inspection }
    q: *pointer*;   { the node physically after node *p* }
    r: *integer*;   { the newly allocated node, or a candidate for this honor }
    t: *integer*;   { temporary register }
  begin *restart*: *p* ← *rover*;   { start at some free node in the ring }
  repeat ⟨ Try to allocate within node *p* and its physical successors, and **goto** *found* if allocation was
        possible 149 ⟩;
    p ← *rlink*(*p*);   { move to the next node in the ring }
  until *p* = *rover*;   { repeat until the whole list has been traversed }
  if *s* = ´10000000000 **then**
    begin *get_node* ← *max_halfword*; **return**;
    end;
  if *lo_mem_max* + 2 < *hi_mem_min* **then**
    if *lo_mem_max* + 2 ≤ *mem_bot* + *max_halfword* **then**
      ⟨ Grow more variable-size memory and **goto** *restart* 148 ⟩;
  overflow("main␣memory␣size", *mem_max* + 1 − *mem_min*);   { sorry, nothing satisfactory is left }
found: *link*(*r*) ← *null*;   { this node is now nonempty }
  stat *var_used* ← *var_used* + *s*;   { maintain usage statistics }
  tats
  get_node ← *r*;
exit: **end**;

148.   The lower part of *mem* grows by 1000 words at a time, unless we are very close to going under. When it grows, we simply link a new node into the available-space list. This method of controlled growth helps to keep the *mem* usage consecutive when T$_{E}$X is implemented on "virtual memory" systems.

⟨ Grow more variable-size memory and **goto** *restart* 148 ⟩ ≡
  begin if *hi_mem_min* − *lo_mem_max* ≥ 1998 **then** *t* ← *lo_mem_max* + 1000
  else *t* ← *lo_mem_max* + 1 + (*hi_mem_min* − *lo_mem_max*) **div** 2;   { *lo_mem_max* + 2 ≤ *t* < *hi_mem_min* }
  p ← *llink*(*rover*); *q* ← *lo_mem_max*; *rlink*(*p*) ← *q*; *llink*(*rover*) ← *q*;
  if *t* > *mem_bot* + *max_halfword* **then** *t* ← *mem_bot* + *max_halfword*;
  rlink(*q*) ← *rover*; *llink*(*q*) ← *p*; *link*(*q*) ← *empty_flag*; *node_size*(*q*) ← *t* − *lo_mem_max*;
  lo_mem_max ← *t*; *link*(*lo_mem_max*) ← *null*; *info*(*lo_mem_max*) ← *null*; *rover* ← *q*; **goto** *restart*;
  end

This code is used in section 147.

149.   Empirical tests show that the routine in this section performs a node-merging operation about 0.75 times per allocation, on the average, after which it finds that $r > p + 1$ about 95% of the time.

⟨ Try to allocate within node p and its physical successors, and **goto** *found* if allocation was possible 149 ⟩ ≡
    $q \leftarrow p + node\_size(p)$;   { find the physical successor }
    while *is_empty*(q) **do**   { merge node p with node q }
        begin $t \leftarrow rlink(q)$;
        if $q = rover$ **then** $rover \leftarrow t$;
        $llink(t) \leftarrow llink(q)$; $rlink(llink(q)) \leftarrow t$;
        $q \leftarrow q + node\_size(q)$;
        end;
    $r \leftarrow q - s$;
    if $r > p + 1$ **then** ⟨ Allocate from the top of node p and **goto** *found* 150 ⟩;
    if $r = p$ **then**
        if $rlink(p) \neq p$ **then** ⟨ Allocate entire node p and **goto** *found* 151 ⟩;
    $node\_size(p) \leftarrow q - p$ { reset the size in case it grew }
This code is used in section 147.

150.   ⟨ Allocate from the top of node p and **goto** *found* 150 ⟩ ≡
    begin $node\_size(p) \leftarrow r - p$;   { store the remaining size }
    $rover \leftarrow p$;   { start searching here next time }
    goto *found*;
    end
This code is used in section 149.

151.   Here we delete node p from the ring, and let *rover* rove around.

⟨ Allocate entire node p and **goto** *found* 151 ⟩ ≡
    begin $rover \leftarrow rlink(p)$; $t \leftarrow llink(p)$; $llink(rover) \leftarrow t$; $rlink(t) \leftarrow rover$; **goto** *found*;
    end
This code is used in section 149.

152.   Conversely, when some variable-size node p of size s is no longer needed, the operation *free_node*(p, s) will make its words available, by inserting p as a new empty node just before where *rover* now points.

procedure *free_node*($p : pointer$; $s : halfword$);   { variable-size node liberation }
    var q: *pointer*;   { $llink(rover)$ }
    begin $node\_size(p) \leftarrow s$; $link(p) \leftarrow empty\_flag$; $q \leftarrow llink(rover)$; $llink(p) \leftarrow q$; $rlink(p) \leftarrow rover$;
        { set both links }
    $llink(rover) \leftarrow p$; $rlink(q) \leftarrow p$;   { insert p into the ring }
    stat $var\_used \leftarrow var\_used - s$; **tats**   { maintain statistics }
    end;

153.   Just before `INITEX` writes out the memory, it sorts the doubly linked available space list. The list is probably very short at such times, so a simple insertion sort is used. The smallest available location will be pointed to by *rover*, the next-smallest by *rlink*(*rover*), etc.

   init procedure *sort_avail*;   { sorts the available variable-size nodes by location }
   var *p, q, r*: *pointer*;   { indices into *mem* }
     old_rover: *pointer*;   { initial *rover* setting }
   begin *p* ← *get_node*(´10000000000);   { merge adjacent free areas }
   p ← *rlink*(*rover*); *rlink*(*rover*) ← *max_halfword*; *old_rover* ← *rover*;
   while *p* ≠ *old_rover* **do** ⟨ Sort *p* into the list starting at *rover* and advance *p* to *rlink*(*p*) 154 ⟩;
   p ← *rover*;
   while *rlink*(*p*) ≠ *max_halfword* **do**
     begin *llink*(*rlink*(*p*)) ← *p*; *p* ← *rlink*(*p*);
     end;
   rlink(*p*) ← *rover*; *llink*(*rover*) ← *p*;
   end;
   tini

154.   The following **while** loop is guaranteed to terminate, since the list that starts at *rover* ends with *max_halfword* during the sorting procedure.

⟨ Sort *p* into the list starting at *rover* and advance *p* to *rlink*(*p*) 154 ⟩ ≡
   if *p* < *rover* **then**
     begin *q* ← *p*; *p* ← *rlink*(*q*); *rlink*(*q*) ← *rover*; *rover* ← *q*;
     end
   else begin *q* ← *rover*;
     while *rlink*(*q*) < *p* **do** *q* ← *rlink*(*q*);
     r ← *rlink*(*p*); *rlink*(*p*) ← *rlink*(*q*); *rlink*(*q*) ← *p*; *p* ← *r*;
     end

This code is used in section 153.

155. Data structures for boxes and their friends.   From the computer's standpoint, TEX's chief mission is to create horizontal and vertical lists. We shall now investigate how the elements of these lists are represented internally as nodes in the dynamic memory.

A horizontal or vertical list is linked together by *link* fields in the first word of each node. Individual nodes represent boxes, glue, penalties, or special things like discretionary hyphens; because of this variety, some nodes are longer than others, and we must distinguish different kinds of nodes. We do this by putting a '*type*' field in the first word, together with the link and an optional '*subtype*'.

> **define** $type(\#) \equiv mem[\#].hh.b0$ { identifies what kind of node this is }
> **define** $subtype(\#) \equiv mem[\#].hh.b1$ { secondary identification in some cases }

156.   A *char_node*, which represents a single character, is the most important kind of node because it accounts for the vast majority of all boxes. Special precautions are therefore taken to ensure that a *char_node* does not take up much memory space. Every such node is one word long, and in fact it is identifiable by this property, since other kinds of nodes have at least two words, and they appear in *mem* locations less than *hi_mem_min*. This makes it possible to omit the *type* field in a *char_node*, leaving us room for two bytes that identify a *font* and a *character* within that font.

Note that the format of a *char_node* allows for up to 256 different fonts and up to 256 characters per font; but most implementations will probably limit the total number of fonts to fewer than 75 per job, and most fonts will stick to characters whose codes are less than 128 (since higher codes are more difficult to access on most keyboards).

Extensions of TEX intended for oriental languages will need even more than 256×256 possible characters, when we consider different sizes and styles of type. It is suggested that Chinese and Japanese fonts be handled by representing such characters in two consecutive *char_node* entries: The first of these has $font = font\_base$, and its *link* points to the second; the second identifies the font and the character dimensions. The saving feature about oriental characters is that most of them have the same box dimensions. The *character* field of the first *char_node* is a "*charext*" that distinguishes between graphic symbols whose dimensions are identical for typesetting purposes. (See the METAFONT manual.) Such an extension of TEX would not be difficult; further details are left to the reader.

In order to make sure that the *character* code fits in a quarterword, TEX adds the quantity *min_quarterword* to the actual code.

Character nodes appear only in horizontal lists, never in vertical lists.

> **define** $is\_char\_node(\#) \equiv (\# \geq hi\_mem\_min)$ { does the argument point to a *char_node*? }
> **define** $font \equiv type$ { the font code in a *char_node* }
> **define** $character \equiv subtype$ { the character code in a *char_node* }

157.   An *hlist_node* stands for a box that was made from a horizontal list. Each *hlist_node* is seven words long, and contains the following fields (in addition to the mandatory *type* and *link*, which we shall not mention explicitly when discussing the other node types): The *height* and *width* and *depth* are scaled integers denoting the dimensions of the box. There is also a *shift_amount* field, a scaled integer indicating how much this box should be lowered (if it appears in a horizontal list), or how much it should be moved to the right (if it appears in a vertical list). There is a *list_ptr* field, which points to the beginning of the list from which this box was fabricated; if *list_ptr* is *null*, the box is empty. Finally, there are three fields that represent the setting of the glue: *glue_set*(*p*) is a word of type *glue_ratio* that represents the proportionality constant for glue setting; *glue_sign*(*p*) is *stretching* or *shrinking* or *normal* depending on whether or not the glue should stretch or shrink or remain rigid; and *glue_order*(*p*) specifies the order of infinity to which glue setting applies (*normal*, *fil*, *fill*, or *filll*). The *subtype* field is not used in T$_{E}$X. In ε-T$_{E}$X the *subtype* field records the box direction mode *box_lr*.

> **define** *hlist_node* = 0   { *type* of hlist nodes }
> **define** *box_node_size* = 7   { number of words to allocate for a box node }
> **define** *width_offset* = 1   { position of *width* field in a box node }
> **define** *depth_offset* = 2   { position of *depth* field in a box node }
> **define** *height_offset* = 3   { position of *height* field in a box node }
> **define** *width*(#) ≡ *mem*[# + *width_offset*].*sc*   { width of the box, in sp }
> **define** *depth*(#) ≡ *mem*[# + *depth_offset*].*sc*   { depth of the box, in sp }
> **define** *height*(#) ≡ *mem*[# + *height_offset*].*sc*   { height of the box, in sp }
> **define** *shift_amount*(#) ≡ *mem*[# + 4].*sc*   { repositioning distance, in sp }
> **define** *list_offset* = 5   { position of *list_ptr* field in a box node }
> **define** *list_ptr*(#) ≡ *link*(# + *list_offset*)   { beginning of the list inside the box }
> **define** *glue_order*(#) ≡ *subtype*(# + *list_offset*)   { applicable order of infinity }
> **define** *glue_sign*(#) ≡ *type*(# + *list_offset*)   { stretching or shrinking }
> **define** *normal* = 0   { the most common case when several cases are named }
> **define** *stretching* = 1   { glue setting applies to the stretch components }
> **define** *shrinking* = 2   { glue setting applies to the shrink components }
> **define** *glue_offset* = 6   { position of *glue_set* in a box node }
> **define** *glue_set*(#) ≡ *mem*[# + *glue_offset*].*gr*   { a word of type *glue_ratio* for glue setting }

158.   The *new_null_box* function returns a pointer to an *hlist_node* in which all subfields have the values corresponding to '\hbox{}'. (The *subtype* field is set to *min_quarterword*, for historic reasons that are no longer relevant.)

function *new_null_box*: *pointer*;   { creates a new box node }
  var *p*: *pointer*;   { the new node }
  begin *p* ← *get_node*(*box_node_size*); *type*(*p*) ← *hlist_node*; *subtype*(*p*) ← *min_quarterword*;
  width(*p*) ← 0; *depth*(*p*) ← 0; *height*(*p*) ← 0; *shift_amount*(*p*) ← 0; *list_ptr*(*p*) ← *null*;
  glue_sign(*p*) ← *normal*; *glue_order*(*p*) ← *normal*; *set_glue_ratio_zero*(*glue_set*(*p*)); *new_null_box* ← *p*;
  end;

159.   A *vlist_node* is like an *hlist_node* in all respects except that it contains a vertical list.

> **define** *vlist_node* = 1   { *type* of vlist nodes }

160. A *rule_node* stands for a solid black rectangle; it has *width*, *depth*, and *height* fields just as in an *hlist_node*. However, if any of these dimensions is -2^{30}, the actual value will be determined by running the rule up to the boundary of the innermost enclosing box. This is called a "running dimension." The *width* is never running in an hlist; the *height* and *depth* are never running in a vlist.

>   **define** *rule_node* = 2 { *type* of rule nodes }
>   **define** *rule_node_size* = 4 { number of words to allocate for a rule node }
>   **define** *null_flag* ≡ −´10000000000 { -2^{30}, signifies a missing item }
>   **define** *is_running*(#) ≡ (# = *null_flag*) { tests for a running dimension }

161. A new rule node is delivered by the *new_rule* function. It makes all the dimensions "running," so you have to change the ones that are not allowed to run.

function *new_rule*: *pointer*;
>   **var** *p*: *pointer*; { the new node }
>   **begin** $p \leftarrow$ *get_node*(*rule_node_size*); *type*(*p*) ← *rule_node*; *subtype*(*p*) ← 0; { the *subtype* is not used }
>   *width*(*p*) ← *null_flag*; *depth*(*p*) ← *null_flag*; *height*(*p*) ← *null_flag*; *new_rule* ← *p*;
>   **end**;

162. Insertions are represented by *ins_node* records, where the *subtype* indicates the corresponding box number. For example, '\insert 250' leads to an *ins_node* whose *subtype* is $250 + min\_quarterword$. The *height* field of an *ins_node* is slightly misnamed; it actually holds the natural height plus depth of the vertical list being inserted. The *depth* field holds the *split_max_depth* to be used in case this insertion is split, and the *split_top_ptr* points to the corresponding *split_top_skip*. The *float_cost* field holds the *floating_penalty* that will be used if this insertion floats to a subsequent page after a split insertion of the same class. There is one more field, the *ins_ptr*, which points to the beginning of the vlist for the insertion.

>   **define** *ins_node* = 3 { *type* of insertion nodes }
>   **define** *ins_node_size* = 5 { number of words to allocate for an insertion }
>   **define** *float_cost*(#) ≡ *mem*[# + 1].*int* { the *floating_penalty* to be used }
>   **define** *ins_ptr*(#) ≡ *info*(# + 4) { the vertical list to be inserted }
>   **define** *split_top_ptr*(#) ≡ *link*(# + 4) { the *split_top_skip* to be used }

163. A *mark_node* has a *mark_ptr* field that points to the reference count of a token list that contains the user's \mark text. In addition there is a *mark_class* field that contains the mark class.

>   **define** *mark_node* = 4 { *type* of a mark node }
>   **define** *small_node_size* = 2 { number of words to allocate for most node types }
>   **define** *mark_ptr*(#) ≡ *link*(# + 1) { head of the token list for a mark }
>   **define** *mark_class*(#) ≡ *info*(# + 1) { the mark class }

164. An *adjust_node*, which occurs only in horizontal lists, specifies material that will be moved out into the surrounding vertical list; i.e., it is used to implement TEX's '\vadjust' operation. The *adjust_ptr* field points to the vlist containing this material.

>   **define** *adjust_node* = 5 { *type* of an adjust node }
>   **define** *adjust_pre* ≡ *subtype* { **if** *subtype* ≠ 0 it is pre-adjustment }
>
>   { *append_list* is used to append a list to *tail* }
>   **define** *append_list*(#) ≡
>   **begin** *link*(*tail*) ← *link*(#); *append_list_end*
>   **define** *append_list_end*(#) ≡ *tail* ← #;
>   **end**
>   **define** *adjust_ptr*(#) ≡ *mem*[# + 1].*int* { vertical list to be moved out of horizontal list }

165. A *ligature_node*, which occurs only in horizontal lists, specifies a character that was fabricated from the interaction of two or more actual characters. The second word of the node, which is called the *lig_char* word, contains *font* and *character* fields just as in a *char_node*. The characters that generated the ligature have not been forgotten, since they are needed for diagnostic messages and for hyphenation; the *lig_ptr* field points to a linked list of character nodes for all original characters that have been deleted. (This list might be empty if the characters that generated the ligature were retained in other nodes.)

The *subtype* field is 0, plus 2 and/or 1 if the original source of the ligature included implicit left and/or right boundaries.

define *ligature_node* = 6   { *type* of a ligature node }
define *lig_char*(#) ≡ # + 1   { the word where the ligature is to be found }
define *lig_ptr*(#) ≡ *link*(*lig_char*(#))   { the list of characters }

166. The *new_ligature* function creates a ligature node having given contents of the *font*, *character*, and *lig_ptr* fields. We also have a *new_lig_item* function, which returns a two-word node having a given *character* field. Such nodes are used for temporary processing as ligatures are being created.

function *new_ligature*(*f*, *c* : *quarterword*; *q* : *pointer*): *pointer*;
  var *p*: *pointer*;   { the new node }
  begin *p* ← *get_node*(*small_node_size*); *type*(*p*) ← *ligature_node*; *font*(*lig_char*(*p*)) ← *f*;
  character(*lig_char*(*p*)) ← *c*; *lig_ptr*(*p*) ← *q*; *subtype*(*p*) ← 0; *new_ligature* ← *p*;
  end;

function *new_lig_item*(*c* : *quarterword*): *pointer*;
  var *p*: *pointer*;   { the new node }
  begin *p* ← *get_node*(*small_node_size*); *character*(*p*) ← *c*; *lig_ptr*(*p*) ← *null*; *new_lig_item* ← *p*;
  end;

167. A *disc_node*, which occurs only in horizontal lists, specifies a "discretionary" line break. If such a break occurs at node *p*, the text that starts at *pre_break*(*p*) will precede the break, the text that starts at *post_break*(*p*) will follow the break, and text that appears in the next *replace_count*(*p*) nodes will be ignored. For example, an ordinary discretionary hyphen, indicated by '\-', yields a *disc_node* with *pre_break* pointing to a *char_node* containing a hyphen, *post_break* = *null*, and *replace_count* = 0. All three of the discretionary texts must be lists that consist entirely of character, kern, box, rule, and ligature nodes.

If *pre_break*(*p*) = *null*, the *ex_hyphen_penalty* will be charged for this break. Otherwise the *hyphen_penalty* will be charged. The texts will actually be substituted into the list by the line-breaking algorithm if it decides to make the break, and the discretionary node will disappear at that time; thus, the output routine sees only discretionaries that were not chosen.

define *disc_node* = 7   { *type* of a discretionary node }
define *replace_count* ≡ *subtype*   { how many subsequent nodes to replace }
define *pre_break* ≡ *llink*   { text that precedes a discretionary break }
define *post_break* ≡ *rlink*   { text that follows a discretionary break }

function *new_disc*: *pointer*;   { creates an empty *disc_node* }
  var *p*: *pointer*;   { the new node }
  begin *p* ← *get_node*(*small_node_size*); *type*(*p*) ← *disc_node*; *replace_count*(*p*) ← 0; *pre_break*(*p*) ← *null*;
  post_break(*p*) ← *null*; *new_disc* ← *p*;
  end;

168.   A *whatsit_node* is a wild card reserved for extensions to TEX. The *subtype* field in its first word says what '*whatsit*' it is, and implicitly determines the node size (which must be 2 or more) and the format of the remaining words. When a *whatsit_node* is encountered in a list, special actions are invoked; knowledgeable people who are careful not to mess up the rest of TEX are able to make TEX do new things by adding code at the end of the program. For example, there might be a 'TEXnicolor' extension to specify different colors of ink, and the whatsit node might contain the desired parameters.

The present implementation of TEX treats the features associated with '`\write`' and '`\special`' as if they were extensions, in order to illustrate how such routines might be coded. We shall defer further discussion of extensions until the end of this program.

define *whatsit_node* = 8   { *type* of special extension nodes }

169.   To support "native" fonts, we build *native_word_node*s, which are variable size whatsits. These have the same *width*, *depth*, and *height* fields as a *box_node*, at offsets 1-3, and then a word containing a size field for the node, a font number, a length, and a glyph count. Then there is a field containing a C pointer to a glyph info array; this and the glyph count are set by *set_native_metrics*. Copying and freeing of these nodes needs to take account of this! This is followed by $2 * length$ bytes, for the actual characters of the string (in UTF-16).

So *native_node_size*, which does not include any space for the actual text, is 6.

0-3 whatsits subtypes are used for open, write, close, special; 4 is language; pdfT$_{E}$X uses up through 30-something, so we use subtypes starting from 40.

There are also *glyph_node*s; these are like *native_word_node*s in having *width*, *depth*, and *height* fields, but then they contain a glyph ID rather than size and length fields, and there's no subsidiary C pointer.

define *native_word_node* = 40   { *subtype* of whatsits that hold *native_font* words }
define *native_word_node_AT* = 41   { a *native_word_node* that should output ActualText }
define *is_native_word_subtype*(#) ≡ ((*subtype*(#) ≥ *native_word_node*) ∧ (*subtype*(#) ≤ *native_word_node_AT*))
define *glyph_node* = 42   { *subtype* in whatsits that hold glyph numbers }
define *native_node_size* = 6   { size of a *native_word* node (plus the actual chars) – see also `xetex.h` }
define *glyph_node_size* = 5
define *native_size*(#) ≡ *mem*[# + 4].*qqqq.b0*
define *native_font*(#) ≡ *mem*[# + 4].*qqqq.b1*
define *native_length*(#) ≡ *mem*[# + 4].*qqqq.b2*
define *native_glyph_count*(#) ≡ *mem*[# + 4].*qqqq.b3*
define *native_glyph_info_ptr*(#) ≡ *mem*[# + 5].*ptr*
define *native_glyph_info_size* = 10
            { number of bytes of info per glyph: 16-bit glyph ID, 32-bit x and y coords }
define *native_glyph* ≡ *native_length*   { in *glyph_node*s, we store the glyph number here }
define *free_native_glyph_info*(#) ≡
        begin if *native_glyph_info_ptr*(#) ≠ *null_ptr* **then**
            begin *libc_free*(*native_glyph_info_ptr*(#)); *native_glyph_info_ptr*(#) ← *null_ptr*;
            native_glyph_count(#) ← 0;
            end
        end

procedure *copy_native_glyph_info*(*src* : *pointer*; *dest* : *pointer*);
  var *glyph_count*: *integer*;
  begin if *native_glyph_info_ptr*(*src*) ≠ *null_ptr* **then**
    begin *glyph_count* ← *native_glyph_count*(*src*);
    native_glyph_info_ptr(*dest*) ← *xmalloc_array*(*char*, *glyph_count* * *native_glyph_info_size*);
    memcpy(*native_glyph_info_ptr*(*dest*), *native_glyph_info_ptr*(*src*), *glyph_count* * *native_glyph_info_size*);
    native_glyph_count(*dest*) ← *glyph_count*;
    end
  end;

170. Picture files are handled with nodes that include fields for the transform associated with the picture, and a pathname for the picture file itself. They also have the *width*, *depth*, and *height* fields of a *box_node* at offsets 1-3. (*depth* will always be zero, as it happens.)

So *pic_node_size*, which does not include any space for the picture file pathname, is 7.

A *pdf_node* is just like *pic_node*, but generate a different XDV file code.

define *pic_node* = 43   { *subtype* in whatsits that hold picture file references }
define *pdf_node* = 44   { *subtype* in whatsits that hold PDF page references }

define *pic_node_size* = 9   { must sync with xetex.h }
define *pic_path_length*(#) ≡ *mem*[# + 4].*hh.b0*
define *pic_page*(#) ≡ *mem*[# + 4].*hh.b1*
define *pic_transform1*(#) ≡ *mem*[# + 5].*hh.lh*
define *pic_transform2*(#) ≡ *mem*[# + 5].*hh.rh*
define *pic_transform3*(#) ≡ *mem*[# + 6].*hh.lh*
define *pic_transform4*(#) ≡ *mem*[# + 6].*hh.rh*
define *pic_transform5*(#) ≡ *mem*[# + 7].*hh.lh*
define *pic_transform6*(#) ≡ *mem*[# + 7].*hh.rh*
define *pic_pdf_box*(#) ≡ *mem*[# + 8].*hh.b0*

171. A *math_node*, which occurs only in horizontal lists, appears before and after mathematical formulas. The *subtype* field is *before* before the formula and *after* after it. There is a *width* field, which represents the amount of surrounding space inserted by \mathsurround.

In addition a *math_node* with *subtype* > *after* and *width* = 0 will be (ab)used to record a regular *math_node* reinserted after being discarded at a line break or one of the text direction primitives (\beginL, \endL, \beginR, and \endR).

define *math_node* = 9   { *type* of a math node }
define *before* = 0   { *subtype* for math node that introduces a formula }
define *after* = 1   { *subtype* for math node that winds up a formula }

define *M_code* = 2
define *begin_M_code* = *M_code* + *before*   { *subtype* for \beginM node }
define *end_M_code* = *M_code* + *after*   { *subtype* for \endM node }
define *L_code* = 4
define *begin_L_code* = *L_code* + *begin_M_code*   { *subtype* for \beginL node }
define *end_L_code* = *L_code* + *end_M_code*   { *subtype* for \endL node }
define *R_code* = *L_code* + *L_code*
define *begin_R_code* = *R_code* + *begin_M_code*   { *subtype* for \beginR node }
define *end_R_code* = *R_code* + *end_M_code*   { *subtype* for \endR node }

define *end_LR*(#) ≡ *odd*(*subtype*(#))
define *end_LR_type*(#) ≡ (*L_code* * (*subtype*(#) **div** *L_code*) + *end_M_code*)
define *begin_LR_type*(#) ≡ (# − *after* + *before*)

function *new_math*(*w* : *scaled*; *s* : *small_number*): *pointer*;
  var *p*: *pointer*;   { the new node }
  begin *p* ← *get_node*(*small_node_size*); *type*(*p*) ← *math_node*; *subtype*(*p*) ← *s*; *width*(*p*) ← *w*;
  new_math ← *p*;
  end;

172.   T_EX makes use of the fact that *hlist_node*, *vlist_node*, *rule_node*, *ins_node*, *mark_node*, *adjust_node*, *ligature_node*, *disc_node*, *whatsit_node*, and *math_node* are at the low end of the type codes, by permitting a break at glue in a list if and only if the *type* of the previous node is less than *math_node*. Furthermore, a node is discarded after a break if its type is *math_node* or more.

> **define** *precedes_break*(#) ≡ (*type*(#) < *math_node*)
> **define** *non_discardable*(#) ≡ (*type*(#) < *math_node*)

173.   A *glue_node* represents glue in a list. However, it is really only a pointer to a separate glue specification, since T_EX makes use of the fact that many essentially identical nodes of glue are usually present. If p points to a *glue_node*, *glue_ptr*(p) points to another packet of words that specify the stretch and shrink components, etc.

Glue nodes also serve to represent leaders; the *subtype* is used to distinguish between ordinary glue (which is called *normal*) and the three kinds of leaders (which are called *a_leaders*, *c_leaders*, and *x_leaders*). The *leader_ptr* field points to a rule node or to a box node containing the leaders; it is set to *null* in ordinary glue nodes.

Many kinds of glue are computed from T_EX's "skip" parameters, and it is helpful to know which parameter has led to a particular glue node. Therefore the *subtype* is set to indicate the source of glue, whenever it originated as a parameter. We will be defining symbolic names for the parameter numbers later (e.g., *line_skip_code* = 0, *baseline_skip_code* = 1, etc.); it suffices for now to say that the *subtype* of parametric glue will be the same as the parameter number, plus one.

In math formulas there are two more possibilities for the *subtype* in a glue node: *mu_glue* denotes an \mskip (where the units are scaled mu instead of scaled pt); and *cond_math_glue* denotes the '\nonscript' feature that cancels the glue node immediately following if it appears in a subscript.

> **define** *glue_node* = 10   { *type* of node that points to a glue specification }
> **define** *cond_math_glue* = 98   { special *subtype* to suppress glue in the next node }
> **define** *mu_glue* = 99   { *subtype* for math glue }
> **define** *a_leaders* = 100   { *subtype* for aligned leaders }
> **define** *c_leaders* = 101   { *subtype* for centered leaders }
> **define** *x_leaders* = 102   { *subtype* for expanded leaders }
> **define** *glue_ptr* ≡ *llink*   { pointer to a glue specification }
> **define** *leader_ptr* ≡ *rlink*   { pointer to box or rule node for leaders }

174.   A glue specification has a halfword reference count in its first word, representing *null* plus the number of glue nodes that point to it (less one). Note that the reference count appears in the same position as the *link* field in list nodes; this is the field that is initialized to *null* when a node is allocated, and it is also the field that is flagged by *empty_flag* in empty nodes.

Glue specifications also contain three *scaled* fields, for the *width*, *stretch*, and *shrink* dimensions. Finally, there are two one-byte fields called *stretch_order* and *shrink_order*; these contain the orders of infinity (*normal*, *fil*, *fill*, or *filll*) corresponding to the stretch and shrink values.

> **define** *glue_spec_size* = 4   { number of words to allocate for a glue specification }
> **define** *glue_ref_count*(#) ≡ *link*(#)   { reference count of a glue specification }
> **define** *stretch*(#) ≡ *mem*[# + 2].*sc*   { the stretchability of this glob of glue }
> **define** *shrink*(#) ≡ *mem*[# + 3].*sc*   { the shrinkability of this glob of glue }
> **define** *stretch_order* ≡ *type*   { order of infinity for stretching }
> **define** *shrink_order* ≡ *subtype*   { order of infinity for shrinking }
> **define** *fil* = 1   { first-order infinity }
> **define** *fill* = 2   { second-order infinity }
> **define** *filll* = 3   { third-order infinity }

⟨ Types in the outer block 18 ⟩ +≡
> *glue_ord* = *normal* .. *filll*;   { infinity to the 0, 1, 2, or 3 power }

175.   Here is a function that returns a pointer to a copy of a glue spec. The reference count in the copy is *null*, because there is assumed to be exactly one reference to the new specification.

function *new_spec*(*p* : *pointer*): *pointer*;   { duplicates a glue specification }
  var *q*: *pointer*;   { the new spec }
  begin *q* ← *get_node*(*glue_spec_size*);
  mem[*q*] ← *mem*[*p*]; *glue_ref_count*(*q*) ← *null*;
  width(*q*) ← *width*(*p*); *stretch*(*q*) ← *stretch*(*p*); *shrink*(*q*) ← *shrink*(*p*); *new_spec* ← *q*;
  end;

176.   And here's a function that creates a glue node for a given parameter identified by its code number; for example, *new_param_glue*(*line_skip_code*) returns a pointer to a glue node for the current \lineskip.

function *new_param_glue*(*n* : *small_number*): *pointer*;
  var *p*: *pointer*;   { the new node }
    q: *pointer*;   { the glue specification }
  begin *p* ← *get_node*(*small_node_size*); *type*(*p*) ← *glue_node*; *subtype*(*p*) ← *n* + 1; *leader_ptr*(*p*) ← *null*;
  q ← ⟨ Current *mem* equivalent of glue parameter number *n* 250 ⟩; *glue_ptr*(*p*) ← *q*;
  incr(*glue_ref_count*(*q*)); *new_param_glue* ← *p*;
  end;

177.   Glue nodes that are more or less anonymous are created by *new_glue*, whose argument points to a glue specification.

function *new_glue*(*q* : *pointer*): *pointer*;
  var *p*: *pointer*;   { the new node }
  begin *p* ← *get_node*(*small_node_size*); *type*(*p*) ← *glue_node*; *subtype*(*p*) ← *normal*;
  leader_ptr(*p*) ← *null*; *glue_ptr*(*p*) ← *q*; *incr*(*glue_ref_count*(*q*)); *new_glue* ← *p*;
  end;

178.   Still another subroutine is needed: This one is sort of a combination of *new_param_glue* and *new_glue*. It creates a glue node for one of the current glue parameters, but it makes a fresh copy of the glue specification, since that specification will probably be subject to change, while the parameter will stay put. The global variable *temp_ptr* is set to the address of the new spec.

function *new_skip_param*(*n* : *small_number*): *pointer*;
  var *p*: *pointer*;   { the new node }
  begin *temp_ptr* ← *new_spec*(⟨ Current *mem* equivalent of glue parameter number *n* 250 ⟩);
  p ← *new_glue*(*temp_ptr*); *glue_ref_count*(*temp_ptr*) ← *null*; *subtype*(*p*) ← *n* + 1; *new_skip_param* ← *p*;
  end;

179. A *kern_node* has a *width* field to specify a (normally negative) amount of spacing. This spacing correction appears in horizontal lists between letters like A and V when the font designer said that it looks better to move them closer together or further apart. A kern node can also appear in a vertical list, when its '*width*' denotes additional spacing in the vertical direction. The *subtype* is either *normal* (for kerns inserted from font information or math mode calculations) or *explicit* (for kerns inserted from \kern and \/ commands) or *acc_kern* (for kerns inserted from non-math accents) or *mu_glue* (for kerns inserted from \mkern specifications in math formulas).

define *kern_node* = 11   { *type* of a kern node }
define *explicit* = 1   { *subtype* of kern nodes from \kern and \/ }
define *acc_kern* = 2   { *subtype* of kern nodes from accents }
define *space_adjustment* = 3
          { *subtype* of kern nodes from \XeTeXinterwordspaceshaping adjustment }

          { memory structure for marginal kerns }
define *margin_kern_node* = 40
define *margin_kern_node_size* = 3
define *margin_char*(#) ≡ *info*(# + 2)   { unused for now; relevant for font expansion }

          { *subtype* of marginal kerns }
define *left_side* ≡ 0
define *right_side* ≡ 1

          { base for lp/rp codes starts from 2: 0 for *hyphen_char*, 1 for *skew_char* }
define *lp_code_base* ≡ 2
define *rp_code_base* ≡ 3
define *max_hlist_stack* = 512   { maximum fill level for *hlist_stack* }
          { maybe good if larger than 2 ∗ *max_quarterword*, so that box nesting level would overflow first }

180. The *new_kern* function creates a kern node having a given width.

function *new_kern*(*w* : *scaled*): *pointer*;
  var *p*: *pointer*;   { the new node }
  begin *p* ← *get_node*(*small_node_size*); *type*(*p*) ← *kern_node*; *subtype*(*p*) ← *normal*; *width*(*p*) ← *w*;
  new_kern ← *p*;
  end;

181. ⟨ Global variables 13 ⟩ +≡
last_leftmost_char: *pointer*;
last_rightmost_char: *pointer*;
hlist_stack: **array** [0 .. *max_hlist_stack*] **of** *pointer*;
          { stack for *find_protchar_left*( ) and *find_protchar_right*( ) }
hlist_stack_level: 0 .. *max_hlist_stack*;   { fill level for *hlist_stack* }
first_p: *pointer*;   { to access the first node of the paragraph }
global_prev_p: *pointer*;
       { to access *prev_p* in *line_break*; should be kept in sync with *prev_p* by *update_prev_p* }

182. A *penalty_node* specifies the penalty associated with line or page breaking, in its *penalty* field. This field is a fullword integer, but the full range of integer values is not used: Any penalty ≥ 10000 is treated as infinity, and no break will be allowed for such high values. Similarly, any penalty ≤ −10000 is treated as negative infinity, and a break will be forced.

define *penalty_node* = 12   { *type* of a penalty node }
define *inf_penalty* = *inf_bad*   { "infinite" penalty value }
define *eject_penalty* = −*inf_penalty*   { "negatively infinite" penalty value }
define *penalty*(#) ≡ *mem*[# + 1].*int*   { the added cost of breaking a list here }

183. Anyone who has been reading the last few sections of the program will be able to guess what comes next.

function *new_penalty*(*m* : *integer*): *pointer*;
 var *p*: *pointer*; { the new node }
 begin *p* ← *get_node*(*small_node_size*); *type*(*p*) ← *penalty_node*; *subtype*(*p*) ← 0;
  { the *subtype* is not used }
 penalty(*p*) ← *m*; *new_penalty* ← *p*;
 end;

184. You might think that we have introduced enough node types by now. Well, almost, but there is one more: An *unset_node* has nearly the same format as an *hlist_node* or *vlist_node*; it is used for entries in \halign or \valign that are not yet in their final form, since the box dimensions are their "natural" sizes before any glue adjustment has been made. The *glue_set* word is not present; instead, we have a *glue_stretch* field, which contains the total stretch of order *glue_order* that is present in the hlist or vlist being boxed. Similarly, the *shift_amount* field is replaced by a *glue_shrink* field, containing the total shrink of order *glue_sign* that is present. The *subtype* field is called *span_count*; an unset box typically contains the data for *qo*(*span_count*) + 1 columns. Unset nodes will be changed to box nodes when alignment is completed.

 define *unset_node* = 13 { *type* for an unset node }
 define *glue_stretch*(#) ≡ *mem*[# + *glue_offset*].*sc* { total stretch in an unset node }
 define *glue_shrink* ≡ *shift_amount* { total shrink in an unset node }
 define *span_count* ≡ *subtype* { indicates the number of spanned columns }

185. In fact, there are still more types coming. When we get to math formula processing we will see that a *style_node* has *type* = 14; and a number of larger type codes will also be defined, for use in math mode only.

186. Warning: If any changes are made to these data structure layouts, such as changing any of the node sizes or even reordering the words of nodes, the *copy_node_list* procedure and the memory initialization code below may have to be changed. Such potentially dangerous parts of the program are listed in the index under 'data structure assumptions'. However, other references to the nodes are made symbolically in terms of the WEB macro definitions above, so that format changes will leave TeX's other algorithms intact.

187. Memory layout. Some areas of *mem* are dedicated to fixed usage, since static allocation is more efficient than dynamic allocation when we can get away with it. For example, locations *mem_bot* to *mem_bot* + 3 are always used to store the specification for glue that is 'Opt plus Opt minus Opt'. The following macro definitions accomplish the static allocation by giving symbolic names to the fixed positions. Static variable-size nodes appear in locations *mem_bot* through *lo_mem_stat_max*, and static single-word nodes appear in locations *hi_mem_stat_min* through *mem_top*, inclusive. It is harmless to let *lig_trick* and *garbage* share the same location of *mem*.

define *zero_glue* ≡ *mem_bot*   { specification for Opt plus Opt minus Opt }
define *fil_glue* ≡ *zero_glue* + *glue_spec_size*   { Opt plus 1fil minus Opt }
define *fill_glue* ≡ *fil_glue* + *glue_spec_size*   { Opt plus 1fill minus Opt }
define *ss_glue* ≡ *fill_glue* + *glue_spec_size*   { Opt plus 1fil minus 1fil }
define *fil_neg_glue* ≡ *ss_glue* + *glue_spec_size*   { Opt plus -1fil minus Opt }
define *lo_mem_stat_max* ≡ *fil_neg_glue* + *glue_spec_size* − 1
         { largest statically allocated word in the variable-size *mem* }

define *page_ins_head* ≡ *mem_top*   { list of insertion data for current page }
define *contrib_head* ≡ *mem_top* − 1   { vlist of items not yet on current page }
define *page_head* ≡ *mem_top* − 2   { vlist for current page }
define *temp_head* ≡ *mem_top* − 3   { head of a temporary list of some kind }
define *hold_head* ≡ *mem_top* − 4   { head of a temporary list of another kind }
define *adjust_head* ≡ *mem_top* − 5   { head of adjustment list returned by *hpack* }
define *active* ≡ *mem_top* − 7   { head of active list in *line_break*, needs two words }
define *align_head* ≡ *mem_top* − 8   { head of preamble list for alignments }
define *end_span* ≡ *mem_top* − 9   { tail of spanned-width lists }
define *omit_template* ≡ *mem_top* − 10   { a constant token list }
define *null_list* ≡ *mem_top* − 11   { permanently empty list }
define *lig_trick* ≡ *mem_top* − 12   { a ligature masquerading as a *char_node* }
define *garbage* ≡ *mem_top* − 12   { used for scrap information }
define *backup_head* ≡ *mem_top* − 13   { head of token list built by *scan_keyword* }
define *pre_adjust_head* ≡ *mem_top* − 14   { head of pre-adjustment list returned by *hpack* }
define *hi_mem_stat_min* ≡ *mem_top* − 14   { smallest statically allocated word in the one-word *mem* }
define *hi_mem_stat_usage* = 15   { the number of one-word nodes always present }

188. The following code gets *mem* off to a good start, when T$_{\text{E}}$X is initializing itself the slow way.

⟨ Local variables for initialization 19 ⟩ +≡
k: *integer*;   { index into *mem*, *eqtb*, etc. }

189. ⟨Initialize table entries (done by INITEX only) 189⟩ ≡
  for $k \leftarrow mem\_bot + 1$ **to** $lo\_mem\_stat\_max$ **do** $mem[k].sc \leftarrow 0$;   {all glue dimensions are zeroed}
  $k \leftarrow mem\_bot$; **while** $k \leq lo\_mem\_stat\_max$ **do**   {set first words of glue specifications}
     begin $glue\_ref\_count(k) \leftarrow null + 1$; $stretch\_order(k) \leftarrow normal$; $shrink\_order(k) \leftarrow normal$;
     $k \leftarrow k + glue\_spec\_size$;
     end;
  $stretch(fil\_glue) \leftarrow unity$; $stretch\_order(fil\_glue) \leftarrow fil$;
  $stretch(fill\_glue) \leftarrow unity$; $stretch\_order(fill\_glue) \leftarrow fill$;
  $stretch(ss\_glue) \leftarrow unity$; $stretch\_order(ss\_glue) \leftarrow fil$;
  $shrink(ss\_glue) \leftarrow unity$; $shrink\_order(ss\_glue) \leftarrow fil$;
  $stretch(fil\_neg\_glue) \leftarrow -unity$; $stretch\_order(fil\_neg\_glue) \leftarrow fil$;
  $rover \leftarrow lo\_mem\_stat\_max + 1$; $link(rover) \leftarrow empty\_flag$;   {now initialize the dynamic memory}
  $node\_size(rover) \leftarrow 1000$;   {which is a 1000-word available node}
  $llink(rover) \leftarrow rover$; $rlink(rover) \leftarrow rover$;
  $lo\_mem\_max \leftarrow rover + 1000$; $link(lo\_mem\_max) \leftarrow null$; $info(lo\_mem\_max) \leftarrow null$;
  for $k \leftarrow hi\_mem\_stat\_min$ **to** mem_top **do** $mem[k] \leftarrow mem[lo\_mem\_max]$;   {clear list heads}
  ⟨Initialize the special list heads and constant nodes 838⟩;
  $avail \leftarrow null$; $mem\_end \leftarrow mem\_top$; $hi\_mem\_min \leftarrow hi\_mem\_stat\_min$;
       {initialize the one-word memory}
  $var\_used \leftarrow lo\_mem\_stat\_max + 1 - mem\_bot$; $dyn\_used \leftarrow hi\_mem\_stat\_usage$;   {initialize statistics}

This code is used in section 8.

190.   If TEX is extended improperly, the *mem* array might get screwed up. For example, some pointers
might be wrong, or some "dead" nodes might not have been freed when the last reference to them disappeared.
Procedures *check_mem* and *search_mem* are available to help diagnose such problems. These procedures
make use of two arrays called *free* and *was_free* that are present only if TEX's debugging routines have been
included. (You may want to decrease the size of *mem* while you are debugging.)

⟨Global variables 13⟩ +≡
  debug *free*: **packed array** [mem_min .. mem_max] **of** *boolean*;   {free cells}
  was_free: **packed array** [mem_min .. mem_max] **of** *boolean*;   {previously free cells}
  $was\_mem\_end, was\_lo\_max, was\_hi\_min$: *pointer*;   {previous mem_end, lo_mem_max, and hi_mem_min}
  panicking: *boolean*;   {do we want to check memory constantly?}
  gubed

191. ⟨Set initial values of key variables 23⟩ +≡
  debug $was\_mem\_end \leftarrow mem\_min$;   {indicate that everything was previously free}
  $was\_lo\_max \leftarrow mem\_min$; $was\_hi\_min \leftarrow mem\_max$; $panicking \leftarrow false$;
  gubed

192.   Procedure *check_mem* makes sure that the available space lists of *mem* are well formed, and it optionally prints out all locations that are reserved now but were free the last time this procedure was called.

> **debug procedure** *check_mem*(*print_locs* : *boolean*);
> **label** *done1*, *done2*;   { loop exits }
> **var** *p, q*: *pointer*;   { current locations of interest in *mem* }
>   *clobbered*: *boolean*;   { is something amiss? }
> **begin for** *p* ← *mem_min* **to** *lo_mem_max* **do** *free*[*p*] ← *false*;   { you can probably do this faster }
> **for** *p* ← *hi_mem_min* **to** *mem_end* **do** *free*[*p*] ← *false*;   { ditto }
> ⟨ Check single-word *avail* list 193 ⟩;
> ⟨ Check variable-size *avail* list 194 ⟩;

  end
This code is used in section 192.

197. The *search_mem* procedure attempts to answer the question "Who points to node p?" In doing so, it fetches *link* and *info* fields of *mem* that might not be of type *two_halves*. Strictly speaking, this is undefined in Pascal, and it can lead to "false drops" (words that seem to point to p purely by coincidence). But for debugging purposes, we want to rule out the places that do *not* point to p, so a few false drops are tolerable.

  debug procedure $search\_mem(p : pointer)$;   { look for pointers to p }
  var q: $integer$;   { current position being searched }

  end; ⟨ Declare procedures that need to be declared forward for pdfTEX 1411 ⟩

199. Displaying boxes. We can reinforce our knowledge of the data structures just introduced by considering two procedures that display a list in symbolic form. The first of these, called *short_display*, is used in "overfull box" messages to give the top-level description of a list. The other one, called *show_node_list*, prints a detailed description of exactly what is in the data structure.

   The philosophy of *short_display* is to ignore the fine points about exactly what is inside boxes, except that ligatures and discretionary breaks are expanded. As a result, *short_display* is a recursive procedure, but the recursion is never more than one level deep.

   A global variable *font_in_short_display* keeps track of the font code that is assumed to be present when *short_display* begins; deviations from this font will be printed.

⟨ Global variables 13 ⟩ +≡
font_in_short_display: *integer*;   { an internal font number }

200.   Boxes, rules, inserts, whatsits, marks, and things in general that are sort of "complicated" are indicated only by printing '[]'.

procedure *short_display*(*p* : *integer*);   { prints highlights of list *p* }
  var *n*: *integer*;   { for replacement counts }
  begin while *p* > *mem_min* **do**
    begin if *is_char_node*(*p*) **then**
      begin if *p* ≤ *mem_end* **then**
        begin if *font*(*p*) ≠ *font_in_short_display* **then**
          begin if (*font*(*p*) < *font_base*) ∨ (*font*(*p*) > *font_max*) **then** *print_char*("∗")
          else ⟨ Print the font identifier for *font*(*p*) 297 ⟩;
          print_char("␣"); *font_in_short_display* ← *font*(*p*);
          end;
        print_ASCII(*qo*(*character*(*p*)));
        end;
      end
    else ⟨ Print a short indication of the contents of node *p* 201 ⟩;
    p ← *link*(*p*);
    end;
  end;

      $decr(n)$;
      end;
    end;
  othercases $do\_nothing$
  endcases
This code is used in section 200.

202. The $show\_node\_list$ routine requires some auxiliary subroutines: one to print a font-and-character combination, one to print a token list without its reference count, and one to print a rule dimension.

procedure $print\_font\_and\_char(p : integer)$; { prints $char\_node$ data }
  begin if $p > mem\_end$ **then** $print\_esc("CLOBBERED.")$
  else begin if $(font(p) < font\_base) \vee (font(p) > font\_max)$ **then** $print\_char("*")$
    else ⟨Print the font identifier for $font(p)$ 297⟩;
    $print\_char("␣")$; $print\_ASCII(qo(character(p)))$;
    end;
  end;

procedure $print\_mark(p : integer)$;   { prints token list data in braces }
  begin $print\_char("\{")$;
  if $(p < hi\_mem\_min) \vee (p > mem\_end)$ **then** $print\_esc("CLOBBERED.")$
  else $show\_token\_list(link(p), null, max\_print\_line - 10)$;
  $print\_char("\}")$;
  end;

procedure $print\_rule\_dimen(d : scaled)$;   { prints dimension in rule node }
  begin if $is\_running(d)$ **then** $print\_char("*")$
  else $print\_scaled(d)$;
  end;

203.   Then there is a subroutine that prints glue stretch and shrink, possibly followed by the name of finite units:

procedure *print_glue*(*d* : *scaled*; *order* : *integer*; *s* : *str_number*);   { prints a glue component }
  begin *print_scaled*(*d*);
  if (*order* < *normal*) ∨ (*order* > *filll*) **then** *print*("foul")
  else if *order* > *normal* **then**
      begin *print*("fil");
      while *order* > *fil* **do**
        begin *print_char*("l"); *decr*(*order*);
        end;
      end
    else if *s* ≠ 0 **then** *print*(*s*);
  end;

204.   The next subroutine prints a whole glue specification.

procedure *print_spec*(*p* : *integer*; *s* : *str_number*);   { prints a glue specification }
  begin if (*p* < *mem_min*) ∨ (*p* ≥ *lo_mem_max*) **then** *print_char*("*")
  else begin *print_scaled*(*width*(*p*));
    if *s* ≠ 0 **then** *print*(*s*);
    if *stretch*(*p*) ≠ 0 **then**
      begin *print*("␣plus␣"); *print_glue*(*stretch*(*p*), *stretch_order*(*p*), *s*);
      end;
    if *shrink*(*p*) ≠ 0 **then**
      begin *print*("␣minus␣"); *print_glue*(*shrink*(*p*), *shrink_order*(*p*), *s*);
      end;
    end;
  end;

205.   We also need to declare some procedures that appear later in this documentation.

⟨ Declare procedures needed for displaying the elements of mlists 733 ⟩
⟨ Declare the procedure called *print_skip_param* 251 ⟩

206.   Since boxes can be inside of boxes, *show_node_list* is inherently recursive, up to a given maximum number of levels. The history of nesting is indicated by the current string, which will be printed at the beginning of each line; the length of this string, namely *cur_length*, is the depth of nesting.
  Recursive calls on *show_node_list* therefore use the following pattern:

  define *node_list_display*(#) ≡
          begin *append_char*("."); *show_node_list*(#); *flush_char*;
          end   { *str_room* need not be checked; see *show_box* below }

207.   A global variable called *depth_threshold* is used to record the maximum depth of nesting for which *show_node_list* will show information. If we have *depth_threshold* = 0, for example, only the top level information will be given and no sublists will be traversed. Another global variable, called *breadth_max*, tells the maximum number of items to show at each level; *breadth_max* had better be positive, or you won't see anything.

⟨ Global variables 13 ⟩ +≡
depth_threshold : *integer*;   { maximum nesting depth in box displays }
breadth_max : *integer*;   { maximum number of items shown at the same list level }

208.   Now we are ready for *show_node_list* itself. This procedure has been written to be "extra robust" in the sense that it should not crash or get into a loop even if the data structures have been messed up by bugs in the rest of the program. You can safely call its parent routine *show_box*(*p*) for arbitrary values of *p* when you are debugging TEX. However, in the presence of bad data, the procedure may fetch a *memory_word* whose variant is different from the way it was stored; for example, it might try to read *mem*[*p*].*hh* when *mem*[*p*] contains a scaled integer, if *p* is a pointer that has been clobbered or chosen at random.

procedure *show_node_list*(*p* : *integer*);   { prints a node list symbolically }
  label *exit*;
  var *n*: *integer*;   { the number of items already printed at this level }
    i: *integer*;   { temp index for printing chars of picfile paths }
    g: *real*;   { a glue ratio, as a floating point number }
  begin if *cur_length* > *depth_threshold* **then**
    begin if *p* > *null* **then** *print*("␣[]");   { indicate that there's been some truncation }
    return;
    end;
  n ← 0;
  while *p* > *mem_min* **do**
    begin *print_ln*; *print_current_string*;   { display the nesting history }
    if *p* > *mem_end* **then**   { pointer out of range }
      begin *print*("Bad␣link,␣display␣aborted."); **return**;
      end;
    incr(*n*);
    if *n* > *breadth_max* **then**   { time to stop }
      begin *print*("etc."); **return**;
      end;
    ⟨ Display node *p* 209 ⟩;
    p ← *link*(*p*);
    end;
exit: **end**;

222. ⟨Display mark p 222⟩ ≡
  begin $print\_esc("mark")$;
  if $mark\_class(p) \neq 0$ **then**
    begin $print\_char("s")$; $print\_int(mark\_class(p))$;
    end;
  $print\_mark(mark\_ptr(p))$;
  end

This code is used in section 209.

223. ⟨Display adjustment p 223⟩ ≡
   begin *print_esc*("vadjust");
   if *adjust_pre*(*p*) ≠ 0 **then** *print*("␣pre␣");
   node_list_display(*adjust_ptr*(*p*));   {recursive call}
   end

This code is used in section 209.

224.   The recursive machinery is started by calling *show_box*.

procedure *show_box*(*p* : *pointer*);
   begin ⟨Assign the values *depth_threshold* ← *show_box_depth* and *breadth_max* ← *show_box_breadth* 262⟩;
   if *breadth_max* ≤ 0 **then** *breadth_max* ← 5;
   if *pool_ptr* + *depth_threshold* ≥ *pool_size* **then** *depth_threshold* ← *pool_size* − *pool_ptr* − 1;
         {now there's enough room for prefix string}
   show_node_list(*p*);   {the show starts at *p*}
   print_ln;
   end;
procedure *short_display_n*(*p*, *m* : *integer*);   {prints highlights of list *p*}
   begin *breadth_max* ← *m*; *depth_threshold* ← *pool_size* − *pool_ptr* − 1; *show_node_list*(*p*);
      {the show starts at *p*}
   end;

225.   Destroying boxes.   When we are done with a node list, we are obliged to return it to free storage, including all of its sublists. The recursive procedure *flush_node_list* does this for us.

226.   First, however, we shall consider two non-recursive procedures that do simpler tasks. The first of these, *delete_token_ref*, is called when a pointer to a token list's reference count is being removed. This means that the token list should disappear if the reference count was *null*, otherwise the count should be decreased by one.

> **define** *token_ref_count*(#) ≡ *info*(#)   { reference count preceding a token list }

procedure *delete_token_ref*(*p* : *pointer*);
>   { *p* points to the reference count of a token list that is losing one reference }
> **begin if** *token_ref_count*(*p*) = *null* **then** *flush_list*(*p*)
> **else** *decr*(*token_ref_count*(*p*));
> **end**;

227.   Similarly, *delete_glue_ref* is called when a pointer to a glue specification is being withdrawn.

> **define** *fast_delete_glue_ref*(#) ≡
>   **begin if** *glue_ref_count*(#) = *null* **then** *free_node*(#, *glue_spec_size*)
>   **else** *decr*(*glue_ref_count*(#));
>   **end**

procedure *delete_glue_ref*(*p* : *pointer*);   { *p* points to a glue specification }
>   *fast_delete_glue_ref*(*p*);

228.   Now we are ready to delete any node list, recursively. In practice, the nodes deleted are usually charnodes (about 2/3 of the time), and they are glue nodes in about half of the remaining cases.

procedure *flush_node_list*(*p* : *pointer*);   { erase list of nodes starting at *p* }
  label *done*;   { go here when node *p* has been freed }
  var *q*: *pointer*;   { successor to node *p* }
  begin while *p* ≠ *null* **do**
    begin *q* ← *link*(*p*);
    if *is_char_node*(*p*) **then** *free_avail*(*p*)
    else begin case *type*(*p*) **of**
      hlist_node, *vlist_node*, *unset_node*: **begin** *flush_node_list*(*list_ptr*(*p*)); *free_node*(*p*, *box_node_size*);
        goto *done*;
        end;
      rule_node: **begin** *free_node*(*p*, *rule_node_size*); **goto** *done*;
        end;
      ins_node: **begin** *flush_node_list*(*ins_ptr*(*p*)); *delete_glue_ref*(*split_top_ptr*(*p*));
        free_node(*p*, *ins_node_size*); **goto** *done*;
        end;
      whatsit_node: ⟨ Wipe out the whatsit node *p* and **goto** *done* 1418 ⟩;
      glue_node: **begin** *fast_delete_glue_ref*(*glue_ptr*(*p*));
        if *leader_ptr*(*p*) ≠ *null* **then** *flush_node_list*(*leader_ptr*(*p*));
        end;
      kern_node, *math_node*, *penalty_node*: *do_nothing*;
      margin_kern_node: **begin** *free_node*(*p*, *margin_kern_node_size*); **goto** *done*;
        end;
      ligature_node: *flush_node_list*(*lig_ptr*(*p*));
      mark_node: *delete_token_ref*(*mark_ptr*(*p*));
      disc_node: **begin** *flush_node_list*(*pre_break*(*p*)); *flush_node_list*(*post_break*(*p*));
        end;
      adjust_node: *flush_node_list*(*adjust_ptr*(*p*));
      ⟨ Cases of *flush_node_list* that arise in mlists only 740 ⟩
      othercases *confusion*("flushing")
      endcases;
      free_node(*p*, *small_node_size*);
    done: **end**;
    p ← *q*;
    end;
  end;

229. Copying boxes.   Another recursive operation that acts on boxes is sometimes needed: The proce-
dure *copy_node_list* returns a pointer to another node list that has the same structure and meaning as the
original. Note that since glue specifications and token lists have reference counts, we need not make copies
of them. Reference counts can never get too large to fit in a halfword, since each pointer to a node is in a
different memory address, and the total number of memory addresses fits in a halfword.

(Well, there actually are also references from outside *mem*; if the *save_stack* is made arbitrarily large, it
would theoretically be possible to break T$_{E}$X by overflowing a reference count. But who would want to do
that?)

> **define** *add_token_ref* (#) ≡ *incr*(*token_ref_count*(#))   { new reference to a token list }
> **define** *add_glue_ref* (#) ≡ *incr*(*glue_ref_count*(#))   { new reference to a glue spec }

230.   The copying procedure copies words en masse without bothering to look at their individual fields. If
the node format changes—for example, if the size is altered, or if some link field is moved to another relative
position—then this code may need to be changed too.

function *copy_node_list* (*p* : *pointer*): *pointer*;
> { makes a duplicate of the node list that starts at *p* and returns a pointer to the new list }
> **var** *h*: *pointer*;   { temporary head of copied list }
>   *q*: *pointer*;   { previous position in new list }
>   *r*: *pointer*;   { current node being fabricated for new list }
>   *words*: 0 . . 5;   { number of words remaining to be copied }
> **begin** *h* ← *get_avail*; *q* ← *h*;
> **while** *p* ≠ *null* **do**
>   **begin** ⟨ Make a copy of node *p* in node *r* 231 ⟩;
>   *link*(*q*) ← *r*; *q* ← *r*; *p* ← *link*(*p*);
>   **end**;
> *link*(*q*) ← *null*; *q* ← *link*(*h*); *free_avail*(*h*); *copy_node_list* ← *q*;
> **end**;

231.   ⟨ Make a copy of node *p* in node *r* 231 ⟩ ≡
> *words* ← 1;   { this setting occurs in more branches than any other }
> **if** *is_char_node*(*p*) **then** *r* ← *get_avail*
> **else** ⟨ Case statement to copy different types and set *words* to the number of initial words not yet
>   copied 232 ⟩;
> **while** *words* > 0 **do**
>   **begin** *decr*(*words*); *mem*[*r* + *words*] ← *mem*[*p* + *words*];
>   **end**

This code is used in section 230.

232. ⟨Case statement to copy different types and set *words* to the number of initial words not yet copied 232⟩ ≡

case *type*(*p*) **of**

hlist_node, *vlist_node*, *unset_node*: **begin** *r* ← *get_node*(*box_node_size*); *mem*[*r* + 6] ← *mem*[*p* + 6];
    mem[*r* + 5] ← *mem*[*p* + 5];   {copy the last two words}

adjust_node: **begin** *r* ← *get_node*(*small_node_size*); *adjust_ptr*(*r*) ← *copy_node_list*(*adjust_ptr*(*p*));
    end;   {*words* = 1 = *small_node_size* − 1}

othercases *confusion*("copying")

endcases

This code is used in section 231.

233.   The command codes.   Before we can go any further, we need to define symbolic names for the internal code numbers that represent the various commands obeyed by TeX. These codes are somewhat arbitrary, but not completely so. For example, the command codes for character types are fixed by the language, since a user says, e.g., '\catcode `\$ = 3' to make $ a math delimiter, and the command code *math_shift* is equal to 3. Some other codes have been made adjacent so that **case** statements in the program need not consider cases that are widely spaced, or so that **case** statements can be replaced by **if** statements.

At any rate, here is the list, for future reference. First come the "catcode" commands, several of which share their numeric codes with ordinary commands when the catcode cannot emerge from TeX's scanning routine.

define *escape* = 0   { escape delimiter (called \ in *The TeXbook*) }
define *relax* = 0   { do nothing (\relax) }
define *left_brace* = 1   { beginning of a group ({) }
define *right_brace* = 2   { ending of a group (}) }
define *math_shift* = 3   { mathematics shift character ($) }
define *tab_mark* = 4   { alignment delimiter (&, \span) }
define *car_ret* = 5   { end of line (*carriage_return*, \cr, \crcr) }
define *out_param* = 5   { output a macro parameter }
define *mac_param* = 6   { macro parameter symbol (#) }
define *sup_mark* = 7   { superscript (^) }
define *sub_mark* = 8   { subscript (_) }
define *ignore* = 9   { characters to ignore (^^@) }
define *endv* = 9   { end of ⟨v_j⟩ list in alignment template }
define *spacer* = 10   { characters equivalent to blank space (␣) }
define *letter* = 11   { characters regarded as letters (A..Z, a..z) }
define *other_char* = 12   { none of the special character types }
define *active_char* = 13   { characters that invoke macros (~) }
define *par_end* = 13   { end of paragraph (\par) }
define *match* = 13   { match a macro parameter }
define *comment* = 14   { characters that introduce comments (%) }
define *end_match* = 14   { end of parameters to macro }
define *stop* = 14   { end of job (\end, \dump) }
define *invalid_char* = 15   { characters that shouldn't appear (^^?) }
define *delim_num* = 15   { specify delimiter numerically (\delimiter) }
define *max_char_code* = 15   { largest catcode for individual characters }

234.   Next are the ordinary run-of-the-mill command codes. Codes that are *min_internal* or more represent internal quantities that might be expanded by '\the'.

 define *char_num* = 16 { character specified numerically (\char) }
 define *math_char_num* = 17 { explicit math code (\mathchar) }
 define *mark* = 18 { mark definition (\mark) }
 define *xray* = 19 { peek inside of TEX (\show, \showbox, etc.) }
 define *make_box* = 20 { make a box (\box, \copy, \hbox, etc.) }
 define *hmove* = 21 { horizontal motion (\moveleft, \moveright) }
 define *vmove* = 22 { vertical motion (\raise, \lower) }
 define *un_hbox* = 23 { unglue a box (\unhbox, \unhcopy) }
 define *un_vbox* = 24 { unglue a box (\unvbox, \unvcopy) }
   { (or \pagediscards, \splitdiscards) }
 define *remove_item* = 25 { nullify last item (\unpenalty, \unkern, \unskip) }
 define *hskip* = 26 { horizontal glue (\hskip, \hfil, etc.) }
 define *vskip* = 27 { vertical glue (\vskip, \vfil, etc.) }
 define *mskip* = 28 { math glue (\mskip) }
 define *kern* = 29 { fixed space (\kern) }
 define *mkern* = 30 { math kern (\mkern) }
 define *leader_ship* = 31 { use a box (\shipout, \leaders, etc.) }
 define *halign* = 32 { horizontal table alignment (\halign) }
 define *valign* = 33 { vertical table alignment (\valign) }
   { or text direction directives (\beginL, etc.) }
 define *no_align* = 34 { temporary escape from alignment (\noalign) }
 define *vrule* = 35 { vertical rule (\vrule) }
 define *hrule* = 36 { horizontal rule (\hrule) }
 define *insert* = 37 { vlist inserted in box (\insert) }
 define *vadjust* = 38 { vlist inserted in enclosing paragraph (\vadjust) }
 define *ignore_spaces* = 39 { gobble *spacer* tokens (\ignorespaces) }
 define *after_assignment* = 40 { save till assignment is done (\afterassignment) }
 define *after_group* = 41 { save till group is done (\aftergroup) }
 define *break_penalty* = 42 { additional badness (\penalty) }
 define *start_par* = 43 { begin paragraph (\indent, \noindent) }
 define *ital_corr* = 44 { italic correction (\/) }
 define *accent* = 45 { attach accent in text (\accent) }
 define *math_accent* = 46 { attach accent in math (\mathaccent) }
 define *discretionary* = 47 { discretionary texts (\-, \discretionary) }
 define *eq_no* = 48 { equation number (\eqno, \leqno) }
 define *left_right* = 49 { variable delimiter (\left, \right) }
   { (or \middle) }
 define *math_comp* = 50 { component of formula (\mathbin, etc.) }
 define *limit_switch* = 51 { diddle limit conventions (\displaylimits, etc.) }
 define *above* = 52 { generalized fraction (\above, \atop, etc.) }
 define *math_style* = 53 { style specification (\displaystyle, etc.) }
 define *math_choice* = 54 { choice specification (\mathchoice) }
 define *non_script* = 55 { conditional math glue (\nonscript) }
 define *vcenter* = 56 { vertically center a vbox (\vcenter) }
 define *case_shift* = 57 { force specific case (\lowercase, \uppercase) }
 define *message* = 58 { send to user (\message, \errmessage) }
 define *extension* = 59 { extensions to TEX (\write, \special, etc.) }
 define *in_stream* = 60 { files for reading (\openin, \closein) }
 define *begin_group* = 61 { begin local grouping (\begingroup) }
 define *end_group* = 62 { end local grouping (\endgroup) }

define *omit* = 63   { omit alignment template (\omit) }
define *ex_space* = 64   { explicit space (\␣) }
define *no_boundary* = 65   { suppress boundary ligatures (\noboundary) }
define *radical* = 66   { square root and similar signs (\radical) }
define *end_cs_name* = 67   { end control sequence (\endcsname) }
define *min_internal* = 68   { the smallest code that can follow \the }
define *char_given* = 68   { character code defined by \chardef }
define *math_given* = 69   { math code defined by \mathchardef }
define *XeTeX_math_given* = 70   { extended math code defined by \Umathchardef }
define *last_item* = 71   { most recent item (\lastpenalty, \lastkern, \lastskip) }
define *max_non_prefixed_command* = 71   { largest command code that can't be \global }

235.   The next codes are special; they all relate to mode-independent assignment of values to TEX's internal registers or tables. Codes that are *max_internal* or less represent internal quantities that might be expanded by '\the'.

define *toks_register* = 72   { token list register (\toks) }
define *assign_toks* = 73   { special token list (\output, \everypar, etc.) }
define *assign_int* = 74   { user-defined integer (\tolerance, \day, etc.) }
define *assign_dimen* = 75   { user-defined length (\hsize, etc.) }
define *assign_glue* = 76   { user-defined glue (\baselineskip, etc.) }
define *assign_mu_glue* = 77   { user-defined muglue (\thinmuskip, etc.) }
define *assign_font_dimen* = 78   { user-defined font dimension (\fontdimen) }
define *assign_font_int* = 79   { user-defined font integer (\hyphenchar, \skewchar) }
define *set_aux* = 80   { specify state info (\spacefactor, \prevdepth) }
define *set_prev_graf* = 81   { specify state info (\prevgraf) }
define *set_page_dimen* = 82   { specify state info (\pagegoal, etc.) }
define *set_page_int* = 83   { specify state info (\deadcycles, \insertpenalties) }
          { (or \interactionmode) }
define *set_box_dimen* = 84   { change dimension of box (\wd, \ht, \dp) }
define *set_shape* = 85   { specify fancy paragraph shape (\parshape) }
          { (or \interlinepenalties, etc.) }
define *def_code* = 86   { define a character code (\catcode, etc.) }
define *XeTeX_def_code* = 87   { \Umathcode, \Udelcode }
define *def_family* = 88   { declare math fonts (\textfont, etc.) }
define *set_font* = 89   { set current font (font identifiers) }
define *def_font* = 90   { define a font file (\font) }
define *register* = 91   { internal register (\count, \dimen, etc.) }
define *max_internal* = 91   { the largest code that can follow \the }
define *advance* = 92   { advance a register or parameter (\advance) }
define *multiply* = 93   { multiply a register or parameter (\multiply) }
define *divide* = 94   { divide a register or parameter (\divide) }
define *prefix* = 95   { qualify a definition (\global, \long, \outer) }
          { (or \protected) }
define *let* = 96   { assign a command code (\let, \futurelet) }
define *shorthand_def* = 97   { code definition (\chardef, \countdef, etc.) }
define *read_to_cs* = 98   { read into a control sequence (\read) }
          { (or \readline) }
define *def* = 99   { macro definition (\def, \gdef, \xdef, \edef) }
define *set_box* = 100   { set a box (\setbox) }
define *hyph_data* = 101   { hyphenation data (\hyphenation, \patterns) }
define *set_interaction* = 102   { define level of interaction (\batchmode, etc.) }
define *max_command* = 102   { the largest command code seen at *big_switch* }

236.   The remaining command codes are extra special, since they cannot get through TEX's scanner to the main control routine. They have been given values higher than *max_command* so that their special nature is easily discernible. The "expandable" commands come first.

> **define** *undefined_cs = max_command + 1*   { initial state of most *eq_type* fields }
> **define** *expand_after = max_command + 2*   { special expansion (\expandafter) }
> **define** *no_expand = max_command + 3*   { special nonexpansion (\noexpand) }
> **define** *input = max_command + 4*   { input a source file (\input, \endinput) }
>   { (or \scantokens) }
> **define** *if_test = max_command + 5*   { conditional text (\if, \ifcase, etc.) }
> **define** *fi_or_else = max_command + 6*   { delimiters for conditionals (\else, etc.) }
> **define** *cs_name = max_command + 7*   { make a control sequence from tokens (\csname) }
> **define** *convert = max_command + 8*   { convert to text (\number, \string, etc.) }
> **define** *the = max_command + 9*   { expand an internal quantity (\the) }
>   { (or \unexpanded, \detokenize) }
> **define** *top_bot_mark = max_command + 10*   { inserted mark (\topmark, etc.) }
> **define** *call = max_command + 11*   { non-long, non-outer control sequence }
> **define** *long_call = max_command + 12*   { long, non-outer control sequence }
> **define** *outer_call = max_command + 13*   { non-long, outer control sequence }
> **define** *long_outer_call = max_command + 14*   { long, outer control sequence }
> **define** *end_template = max_command + 15*   { end of an alignment template }
> **define** *dont_expand = max_command + 16*   { the following token was marked by \noexpand }
> **define** *glue_ref = max_command + 17*   { the equivalent points to a glue specification }
> **define** *shape_ref = max_command + 18*   { the equivalent points to a parshape specification }
> **define** *box_ref = max_command + 19*   { the equivalent points to a box node, or is *null* }
> **define** *data = max_command + 20*   { the equivalent is simply a halfword number }

237. **The semantic nest.** T$_E$X is typically in the midst of building many lists at once. For example, when a math formula is being processed, T$_E$X is in math mode and working on an mlist; this formula has temporarily interrupted T$_E$X from being in horizontal mode and building the hlist of a paragraph; and this paragraph has temporarily interrupted T$_E$X from being in vertical mode and building the vlist for the next page of a document. Similarly, when a \vbox occurs inside of an \hbox, T$_E$X is temporarily interrupted from working in restricted horizontal mode, and it enters internal vertical mode. The "semantic nest" is a stack that keeps track of what lists and modes are currently suspended.

At each level of processing we are in one of six modes:

vmode stands for vertical mode (the page builder);
hmode stands for horizontal mode (the paragraph builder);
mmode stands for displayed formula mode;
$-vmode$ stands for internal vertical mode (e.g., in a \vbox);
$-hmode$ stands for restricted horizontal mode (e.g., in an \hbox);
$-mmode$ stands for math formula mode (not displayed).

The mode is temporarily set to zero while processing \write texts.

Numeric values are assigned to *vmode*, *hmode*, and *mmode* so that T$_E$X's "big semantic switch" can select the appropriate thing to do by computing the value $abs(mode) + cur\_cmd$, where *mode* is the current mode and *cur_cmd* is the current command code.

> **define** $vmode = 1$ { vertical mode }
> **define** $hmode = vmode + max\_command + 1$ { horizontal mode }
> **define** $mmode = hmode + max\_command + 1$ { math mode }

procedure *print_mode*(m : integer);   { prints the mode represented by m }
  begin if $m > 0$ **then**
    case m **div** $(max\_command + 1)$ **of**
    0: *print*("vertical");
    1: *print*("horizontal");
    2: *print*("display␣math");
    end
  else if $m = 0$ **then** *print*("no")
    else case $(-m)$ **div** $(max\_command + 1)$ **of**
      0: *print*("internal␣vertical");
      1: *print*("restricted␣horizontal");
      2: *print*("math");
      end;
  print("␣mode");
  end;

238.   The state of affairs at any semantic level can be represented by five values:

mode is the number representing the semantic mode, as just explained.

head is a *pointer* to a list head for the list being built; *link*(*head*) therefore points to the first element of the list, or to *null* if the list is empty.

tail is a *pointer* to the final node of the list being built; thus, *tail* = *head* if and only if the list is empty.

prev_graf is the number of lines of the current paragraph that have already been put into the present vertical list.

aux is an auxiliary *memory_word* that gives further information that is needed to characterize the situation.

In vertical mode, *aux* is also known as *prev_depth*; it is the scaled value representing the depth of the previous box, for use in baseline calculations, or it is ≤ −1000pt if the next box on the vertical list is to be exempt from baseline calculations. In horizontal mode, *aux* is also known as *space_factor* and *clang*; it holds the current space factor used in spacing calculations, and the current language used for hyphenation. (The value of *clang* is undefined in restricted horizontal mode.) In math mode, *aux* is also known as *incompleat_noad*; if not *null*, it points to a record that represents the numerator of a generalized fraction for which the denominator is currently being formed in the current list.

There is also a sixth quantity, *mode_line*, which correlates the semantic nest with the user's input; *mode_line* contains the source line number at which the current level of nesting was entered. The negative of this line number is the *mode_line* at the level of the user's output routine.

A seventh quantity, *eTeX_aux*, is used by the extended features ε-TEX. In vertical modes it is known as *LR_save* and holds the LR stack when a paragraph is interrupted by a displayed formula. In display math mode it is known as *LR_box* and holds a pointer to a prototype box for the display. In math mode it is known as *delim_ptr* and points to the most recent *left_noad* or *middle_noad* of a *math_left_group*.

In horizontal mode, the *prev_graf* field is used for initial language data.

The semantic nest is an array called *nest* that holds the *mode*, *head*, *tail*, *prev_graf*, *aux*, and *mode_line* values for all semantic levels below the currently active one. Information about the currently active level is kept in the global quantities *mode*, *head*, *tail*, *prev_graf*, *aux*, and *mode_line*, which live in a Pascal record that is ready to be pushed onto *nest* if necessary.

define *ignore_depth* ≡ −65536000   { *prev_depth* value that is ignored }

⟨ Types in the outer block 18 ⟩ +≡
   list_state_record = **record** *mode_field*: −*mmode* .. *mmode*; *head_field*, *tail_field*: *pointer*;
      eTeX_aux_field: *pointer*;
      pg_field, *ml_field*: *integer*; *aux_field*: *memory_word*;
      end;

239.   **define** $mode \equiv cur\_list.mode\_field$ { current mode }
  define $head \equiv cur\_list.head\_field$ { header node of current list }
  define $tail \equiv cur\_list.tail\_field$ { final node on current list }
  define $eTeX\_aux \equiv cur\_list.eTeX\_aux\_field$ { auxiliary data for ε-T$_{\mathcal{E}}$X }
  define $LR\_save \equiv eTeX\_aux$ { LR stack when a paragraph is interrupted }
  define $LR\_box \equiv eTeX\_aux$ { prototype box for display }
  define $delim\_ptr \equiv eTeX\_aux$ { most recent left or right noad of a math left group }
  define $prev\_graf \equiv cur\_list.pg\_field$ { number of paragraph lines accumulated }
  define $aux \equiv cur\_list.aux\_field$ { auxiliary data about the current list }
  define $prev\_depth \equiv aux.sc$ { the name of aux in vertical mode }
  define $space\_factor \equiv aux.hh.lh$ { part of aux in horizontal mode }
  define $clang \equiv aux.hh.rh$ { the other part of aux in horizontal mode }
  define $incompleat\_noad \equiv aux.int$ { the name of aux in math mode }
  define $mode\_line \equiv cur\_list.ml\_field$ { source file line number at beginning of list }
⟨ Global variables 13 ⟩ +≡
$nest$: **array** $[0 .. nest\_size]$ **of** $list\_state\_record$;
$nest\_ptr$: $0 .. nest\_size$;   { first unused location of $nest$ }
max_nest_stack: $0 .. nest\_size$;   { maximum of $nest\_ptr$ when pushing }
cur_list: $list\_state\_record$;   { the "top" semantic state }
$shown\_mode$: $-mmode .. mmode$;   { most recent mode shown by \tracingcommands }

240.   Here is a common way to make the current list grow:
  define $tail\_append(\#) \equiv$
          begin $link(tail) \leftarrow \#$; $tail \leftarrow link(tail)$;
          end

241.   We will see later that the vertical list at the bottom semantic level is split into two parts; the "current page" runs from $page\_head$ to $page\_tail$, and the "contribution list" runs from $contrib\_head$ to $tail$ of semantic level zero. The idea is that contributions are first formed in vertical mode, then "contributed" to the current page (during which time the page-breaking decisions are made). For now, we don't need to know any more details about the page-building process.

⟨ Set initial values of key variables 23 ⟩ +≡
  $nest\_ptr \leftarrow 0$; $max\_nest\_stack \leftarrow 0$; $mode \leftarrow vmode$; $head \leftarrow contrib\_head$; $tail \leftarrow contrib\_head$;
  $eTeX\_aux \leftarrow null$; $prev\_depth \leftarrow ignore\_depth$; $mode\_line \leftarrow 0$; $prev\_graf \leftarrow 0$; $shown\_mode \leftarrow 0$;
  ⟨ Start a new current page 1045 ⟩;

242.   When T$_{\mathcal{E}}$X's work on one level is interrupted, the state is saved by calling $push\_nest$. This routine changes $head$ and $tail$ so that a new (empty) list is begun; it does not change $mode$ or aux.

procedure $push\_nest$;   { enter a new semantic level, save the old }
  begin if $nest\_ptr > max\_nest\_stack$ **then**
    begin $max\_nest\_stack \leftarrow nest\_ptr$;
    if $nest\_ptr = nest\_size$ **then** $overflow("semantic_\sqcup nest_\sqcup size", nest\_size)$;
    end;
  $nest[nest\_ptr] \leftarrow cur\_list$;   { stack the record }
  $incr(nest\_ptr)$; $head \leftarrow get\_avail$; $tail \leftarrow head$; $prev\_graf \leftarrow 0$; $mode\_line \leftarrow line$; $eTeX\_aux \leftarrow null$;
  end;

243.   Conversely, when TEX is finished on the current level, the former state is restored by calling *pop_nest*. This routine will never be called at the lowest semantic level, nor will it be called unless *head* is a node that should be returned to free memory.

procedure *pop_nest*;   { leave a semantic level, re-enter the old }
  begin *free_avail*(*head*); *decr*(*nest_ptr*); *cur_list* ← *nest*[*nest_ptr*];
  end;

244.   Here is a procedure that displays what TEX is working on, at all levels.

procedure *print_totals*; **forward**;
procedure *show_activities*;
  var *p*: 0 .. *nest_size*;   { index into *nest* }
    m: −*mmode* .. *mmode*;   { mode }
    a: *memory_word*;   { auxiliary }
    q, r: *pointer*;   { for showing the current page }
    t: *integer*;   { ditto }
  begin *nest*[*nest_ptr*] ← *cur_list*;   { put the top level into the array }
  print_nl(""); *print_ln*;
  for *p* ← *nest_ptr* **downto** 0 **do**
    begin *m* ← *nest*[*p*].*mode_field*; *a* ← *nest*[*p*].*aux_field*; *print_nl*("###␣"); *print_mode*(*m*);
    print("␣entered␣at␣line␣"); *print_int*(*abs*(*nest*[*p*].*ml_field*));
    if *m* = *hmode* **then**
      if *nest*[*p*].*pg_field* ≠ ´40600000 **then**
        begin *print*("␣(language"); *print_int*(*nest*[*p*].*pg_field* **mod** ´200000); *print*(":hyphenmin");
        print_int(*nest*[*p*].*pg_field* **div** ´20000000); *print_char*(",");
        print_int((*nest*[*p*].*pg_field* **div** ´200000) **mod** ´100); *print_char*(")");
        end;
    if *nest*[*p*].*ml_field* < 0 **then** *print*("␣(\output␣routine)");
    if *p* = 0 **then**
      begin ⟨ Show the status of the current page 1040 ⟩;
      if *link*(*contrib_head*) ≠ *null* **then** *print_nl*("###␣recent␣contributions:");
      end;
    show_box(*link*(*nest*[*p*].*head_field*)); ⟨ Show the auxiliary field, *a* 245 ⟩;
    end;
  end;

245. ⟨Show the auxiliary field, a 245⟩ ≡

  case $abs(m)$ **div** $(max\_command + 1)$ **of**

This code is used in section 244.

246.   The table of equivalents.   Now that we have studied the data structures for TeX's semantic routines, we ought to consider the data structures used by its syntactic routines. In other words, our next concern will be the tables that TeX looks at when it is scanning what the user has written.

The biggest and most important such table is called *eqtb*. It holds the current "equivalents" of things; i.e., it explains what things mean or what their current values are, for all quantities that are subject to the nesting structure provided by TeX's grouping mechanism. There are six parts to *eqtb*:

1) *eqtb*[*active_base* .. (*hash_base* − 1)] holds the current equivalents of single-character control sequences.

2) *eqtb*[*hash_base* .. (*glue_base* − 1)] holds the current equivalents of multiletter control sequences.

3) *eqtb*[*glue_base* .. (*local_base* − 1)] holds the current equivalents of glue parameters like the current baselineskip.

4) *eqtb*[*local_base* .. (*int_base* − 1)] holds the current equivalents of local halfword quantities like the current box registers, the current "catcodes," the current font, and a pointer to the current paragraph shape.

5) *eqtb*[*int_base* .. (*dimen_base* − 1)] holds the current equivalents of fullword integer parameters like the current hyphenation penalty.

6) *eqtb*[*dimen_base* .. *eqtb_size*] holds the current equivalents of fullword dimension parameters like the current hsize or amount of hanging indentation.

Note that, for example, the current amount of baselineskip glue is determined by the setting of a particular location in region 3 of *eqtb*, while the current meaning of the control sequence '`\baselineskip`' (which might have been changed by `\def` or `\let`) appears in region 2.

247.   Each entry in *eqtb* is a *memory_word*. Most of these words are of type *two_halves*, and subdivided into three fields:

1) The *eq_level* (a quarterword) is the level of grouping at which this equivalent was defined. If the level is *level_zero*, the equivalent has never been defined; *level_one* refers to the outer level (outside of all groups), and this level is also used for global definitions that never go away. Higher levels are for equivalents that will disappear at the end of their group.

2) The *eq_type* (another quarterword) specifies what kind of entry this is. There are many types, since each TeX primitive like `\hbox`, `\def`, etc., has its own special code. The list of command codes above includes all possible settings of the *eq_type* field.

3) The *equiv* (a halfword) is the current equivalent value. This may be a font number, a pointer into *mem*, or a variety of other things.

    define *eq_level_field*(#) ≡ #.*hh.b1*
    define *eq_type_field*(#) ≡ #.*hh.b0*
    define *equiv_field*(#) ≡ #.*hh.rh*
    define *eq_level*(#) ≡ *eq_level_field*(*eqtb*[#])   { level of definition }
    define *eq_type*(#) ≡ *eq_type_field*(*eqtb*[#])   { command code for equivalent }
    define *equiv*(#) ≡ *equiv_field*(*eqtb*[#])   { equivalent value }
    define *level_zero* = *min_quarterword*   { level for undefined quantities }
    define *level_one* = *level_zero* + 1   { outermost level for defined quantities }

248.   Many locations in *eqtb* have symbolic names. The purpose of the next paragraphs is to define these names, and to set up the initial values of the equivalents.

In the first region we have *number_usvs* equivalents for "active characters" that act as control sequences, followed by *too_big_char* equivalents for single-character control sequences.

Then comes region 2, which corresponds to the hash table that we will define later. The maximum address in this region is used for a dummy control sequence that is perpetually undefined. There also are several locations for control sequences that are perpetually defined (since they are used in error recovery).

define *active_base* = 1   { beginning of region 1, for active character equivalents }
define *single_base* = *active_base* + *number_usvs*   { equivalents of one-character control sequences }
        { single-character sequence whose character code is > ″FFFF are treated as a multiletter
            sequence, because UTF-16 is used in the string pool. }
define *null_cs* = *single_base* + *too_big_char*   { equivalent of \csname\endcsname }
define *hash_base* = *null_cs* + 1   { beginning of region 2, for the hash table }
define *frozen_control_sequence* = *hash_base* + *hash_size*   { for error recovery }
define *frozen_protection* = *frozen_control_sequence*   { inaccessible but definable }
define *frozen_cr* = *frozen_control_sequence* + 1   { permanent '\cr' }
define *frozen_end_group* = *frozen_control_sequence* + 2   { permanent '\endgroup' }
define *frozen_right* = *frozen_control_sequence* + 3   { permanent '\right' }
define *frozen_fi* = *frozen_control_sequence* + 4   { permanent '\fi' }
define *frozen_end_template* = *frozen_control_sequence* + 5   { permanent '\endtemplate' }
define *frozen_endv* = *frozen_control_sequence* + 6   { second permanent '\endtemplate' }
define *frozen_relax* = *frozen_control_sequence* + 7   { permanent '\relax' }
define *end_write* = *frozen_control_sequence* + 8   { permanent '\endwrite' }
define *frozen_dont_expand* = *frozen_control_sequence* + 9   { permanent '\notexpanded:' }
define *prim_size* = 2100   { maximum number of primitives }
define *frozen_null_font* = *frozen_control_sequence* + 10   { permanent '\nullfont' }
define *frozen_primitive* = *frozen_control_sequence* + 11   { permanent '\pdfprimitive' }
define *prim_eqtb_base* = *frozen_primitive* + 1
define *font_id_base* = *frozen_null_font* − *font_base*   { begins table of 257 permanent font identifiers }
define *undefined_control_sequence* = *frozen_null_font* + 257   { dummy location }
define *glue_base* = *undefined_control_sequence* + 1   { beginning of region 3 }

⟨ Initialize table entries (done by INITEX only) 189 ⟩ +≡
  eq_type(*undefined_control_sequence*) ← *undefined_cs*; *equiv*(*undefined_control_sequence*) ← *null*;
  eq_level(*undefined_control_sequence*) ← *level_zero*;
  for *k* ← *active_base* **to** *undefined_control_sequence* − 1 **do** *eqtb*[*k*] ← *eqtb*[*undefined_control_sequence*];

249.   Here is a routine that displays the current meaning of an *eqtb* entry in region 1 or 2. (Similar routines for the other regions will appear below.)

⟨ Show equivalent *n*, in region 1 or 2 249 ⟩ ≡
  begin *sprint_cs*(*n*); *print_char*("="); *print_cmd_chr*(*eq_type*(*n*), *equiv*(*n*));
  if *eq_type*(*n*) ≥ *call* **then**
    begin *print_char*(":"); *show_token_list*(*link*(*equiv*(*n*)), *null*, 32);
    end;
  end

This code is used in section 278.

250.   Region 3 of *eqtb* contains the *number_regs* `\skip` registers, as well as the glue parameters defined here. It is important that the "muskip" parameters have larger numbers than the others.

258.   We initialize most things to null or undefined values. An undefined font is represented by the internal code *font_base*.

However, the character code tables are given initial values based on the conventional interpretation of ASCII code. These initial values should not be changed when TEX is adapted for use with non-English languages; all changes to the initialization conventions should be made in format packages, not in TEX itself, so that global interchange of formats is possible.

> **define** *null_font* ≡ *font_base*

265. ⟨Cases of $print\_cmd\_chr$ for symbolic printing of primitives 253⟩ +≡
$assign\_int$: **if** $chr\_code < count\_base$ **then** $print\_param(chr\_code - int\_base)$
  else begin $print\_esc($"count"$); print\_int(chr\_code - count\_base);$
    end;

266.   The integer parameters should really be initialized by a macro package; the following initialization does the minimum to keep TEX from complete failure.

⟨Initialize table entries (done by INITEX only) 189⟩ +≡
  for $k \leftarrow int\_base$ **to** $del\_code\_base - 1$ **do** $eqtb[k].int \leftarrow 0;$
  $mag \leftarrow 1000; tolerance \leftarrow 10000; hang\_after \leftarrow 1; max\_dead\_cycles \leftarrow 25; escape\_char \leftarrow$ "\";
  $end\_line\_char \leftarrow carriage\_return;$
  for $k \leftarrow 0$ **to** $number\_usvs - 1$ **do** $del\_code(k) \leftarrow -1;$
  $del\_code($"."$) \leftarrow 0;$ { this null delimiter is used in error recovery }

267.   The following procedure, which is called just before TEX initializes its input and output, establishes the initial values of the date and time. Since standard Pascal cannot provide such information, something special is needed. The program here simply assumes that suitable values appear in the global variables sys_time, sys_day, sys_month, and sys_year (which are initialized to noon on 4 July 1776, in case the implementor is careless).

procedure $fix\_date\_and\_time;$
  begin $sys\_time \leftarrow 12 * 60; sys\_day \leftarrow 4; sys\_month \leftarrow 7; sys\_year \leftarrow 1776;$ { self-evident truths }
  $time \leftarrow sys\_time;$ { minutes since midnight }
  $day \leftarrow sys\_day;$ { day of the month }
  $month \leftarrow sys\_month;$ { month of the year }
  $year \leftarrow sys\_year;$ { Anno Domini }
  end;

268. ⟨Show equivalent n, in region 5 268⟩ ≡
  begin if $n < count\_base$ **then** $print\_param(n - int\_base)$
  else if $n < del\_code\_base$ **then**
      begin $print\_esc($"count"$); print\_int(n - count\_base);$
      end
    else begin $print\_esc($"delcode"$); print\_int(n - del\_code\_base);$
      end;
  $print\_char($"="$); print\_int(eqtb[n].int);$
  end
This code is used in section 278.

269. ⟨Set variable c to the current escape character 269⟩ ≡
  $c \leftarrow escape\_char$
This code is used in section 67.

270. ⟨Character s is the current new-line character 270⟩ ≡
  $s = new\_line\_char$

This code is used in sections 59 and 63.

271. TEX is occasionally supposed to print diagnostic information that goes only into the transcript file, unless *tracing_online* is positive. Here are two routines that adjust the destination of print commands:

procedure *begin_diagnostic*;   { prepare to do some tracing }
  begin *old_setting* ← *selector*;
  if $(tracing\_online \leq 0) \wedge (selector = term\_and\_log)$ **then**
    begin *decr*(*selector*);
    if *history* = *spotless* **then** *history* ← *warning_issued*;
    end;
  end;

procedure *end_diagnostic*(*blank_line* : *boolean*);   { restore proper conditions after tracing }
  begin *print_nl*("");
  if *blank_line* **then** *print_ln*;
  selector ← *old_setting*;
  end;

272. Of course we had better declare a few more global variables, if the previous routines are going to work.

⟨Global variables 13⟩ +≡
old_setting: $0 .. max\_selector$;
sys_time, *sys_day*, *sys_month*, *sys_year*: *integer*;   { date and time supplied by external system }

273.   The final region of *eqtb* contains the dimension parameters defined here, and the *number_regs* \dimen
registers.

        else if *n* < *dimen_base* **then** ⟨Show equivalent *n*, in region 5 268 ⟩
          else if *n* ≤ *eqtb_size* **then** ⟨Show equivalent *n*, in region 6 277 ⟩
            else *print_char*("?");   { this can't happen either }
  end;
  tats

279.   The last two regions of *eqtb* have fullword values instead of the three fields *eq_level*, *eq_type*, and *equiv*. An *eq_type* is unnecessary, but TEX needs to store the *eq_level* information in another array called *xeq_level*.

⟨ Global variables 13 ⟩ +≡
eqtb: **array** [*active_base* .. *eqtb_size*] **of** *memory_word*;
xeq_level: **array** [*int_base* .. *eqtb_size*] **of** *quarterword*;

280.   ⟨ Set initial values of key variables 23 ⟩ +≡
  for *k* ← *int_base* **to** *eqtb_size* **do** *xeq_level*[*k*] ← *level_one*;

281.   When the debugging routine *search_mem* is looking for pointers having a given value, it is interested only in regions 1 to 3 of *eqtb*, and in the first part of region 4.

⟨ Search *eqtb* for equivalents equal to *p* 281 ⟩ ≡
  for *q* ← *active_base* **to** *box_base* + *biggest_reg* **do**
    begin if *equiv*(*q*) = *p* **then**
      begin *print_nl*("EQUIV("); *print_int*(*q*); *print_char*(")");
      end;
    end

This code is used in section 197.

282.   The hash table.   Control sequences are stored and retrieved by means of a fairly standard hash table algorithm called the method of "coalescing lists" (cf. Algorithm 6.4C in *The Art of Computer Programming*). Once a control sequence enters the table, it is never removed, because there are complicated situations involving \gdef where the removal of a control sequence at the end of a group would be a mistake preventable only by the introduction of a complicated reference-count mechanism.

The actual sequence of letters forming a control sequence identifier is stored in the *str_pool* array together with all the other strings. An auxiliary array *hash* consists of items with two halfword fields per word. The first of these, called $next(p)$, points to the next identifier belonging to the same coalesced list as the identifier corresponding to p; and the other, called $text(p)$, points to the *str_start* entry for p's identifier. If position p of the hash table is empty, we have $text(p) = 0$; if position p is either empty or the end of a coalesced hash list, we have $next(p) = 0$. An auxiliary pointer variable called *hash_used* is maintained in such a way that all locations $p \geq hash\_used$ are nonempty. The global variable *cs_count* tells how many multiletter control sequences have been defined, if statistics are being kept.

A global boolean variable called *no_new_control_sequence* is set to *true* during the time that new hash table entries are forbidden.

> **define** $next(\#) \equiv hash[\#].lh$ { link for coalesced lists }
> **define** $text(\#) \equiv hash[\#].rh$ { string number for control sequence name }
> **define** $hash\_is\_full \equiv (hash\_used = hash\_base)$ { test if all positions are occupied }
> **define** $font\_id\_text(\#) \equiv text(font\_id\_base + \#)$ { a frozen font identifier's name }

⟨ Global variables 13 ⟩ +≡
hash: **array** [*hash_base* .. *undefined_control_sequence* − 1] **of** *two_halves*;   { the hash table }
hash_used: *pointer*;   { allocation pointer for *hash* }
no_new_control_sequence: *boolean*;   { are new identifiers legal? }
cs_count: *integer*;   { total number of known identifiers }

283.   Primitive support needs a few extra variables and definitions

> **define** $prim\_prime = 1777$ { about 85% of *primitive_size* }
> **define** $prim\_base = 1$
> **define** $prim\_next(\#) \equiv prim[\#].lh$ { link for coalesced lists }
> **define** $prim\_text(\#) \equiv prim[\#].rh$ { string number for control sequence name, plus one }
> **define** $prim\_is\_full \equiv (prim\_used = prim\_base)$ { test if all positions are occupied }
> **define** $prim\_eq\_level\_field(\#) \equiv \#.hh.b1$
> **define** $prim\_eq\_type\_field(\#) \equiv \#.hh.b0$
> **define** $prim\_equiv\_field(\#) \equiv \#.hh.rh$
> **define** $prim\_eq\_level(\#) \equiv prim\_eq\_level\_field(eqtb[prim\_eqtb\_base + \#])$ { level of definition }
> **define** $prim\_eq\_type(\#) \equiv prim\_eq\_type\_field(eqtb[prim\_eqtb\_base + \#])$ { command code for equivalent }
> **define** $prim\_equiv(\#) \equiv prim\_equiv\_field(eqtb[prim\_eqtb\_base + \#])$ { equivalent value }
> **define** $undefined\_primitive = 0$

⟨ Global variables 13 ⟩ +≡
prim: **array** [0 .. *prim_size*] **of** *two_halves*;   { the primitives table }
prim_used: *pointer*;   { allocation pointer for *prim* }

284.   ⟨ Set initial values of key variables 23 ⟩ +≡
no_new_control_sequence ← *true*;   { new identifiers are usually forbidden }
$prim\_next(0) \leftarrow 0$; $prim\_text(0) \leftarrow 0$;

       end
     end;
   $text(p) \leftarrow make\_string$; $pool\_ptr \leftarrow pool\_ptr + d$;
   stat $incr(cs\_count)$; **tats**
   end

This code is used in section 286.

288. The value of $hash\_prime$ should be roughly 85% of $hash\_size$, and it should be a prime number. The theory of hashing tells us to expect fewer than two table probes, on the average, when the search is successful. [See J. S. Vitter, *Journal of the ACM* **30** (1983), 231–258.]

⟨Compute the hash code h 288⟩ ≡

   $h \leftarrow 0$;
   for $k \leftarrow j$ **to** $j + l - 1$ **do**
     begin $h \leftarrow h + h + buffer[k]$;
     while $h \geq hash\_prime$ **do** $h \leftarrow h - hash\_prime$;
     end

This code is used in section 286.

289.   Here is the subroutine that searches the primitive table for an identifier

function *prim_lookup*(*s* : *str_number*): *pointer*;   { search the primitives table }
  label *found*;   { go here if you found it }
  var *h*: *integer*;   { hash code }
    p: *pointer*;   { index in *hash* array }
    k: *pointer*;   { index in string pool }
    j, *l*: *integer*;
  begin if $s \leq biggest\_char$ **then**
    begin if $s < 0$ **then**
      begin $p \leftarrow undefined\_primitive$; **goto** *found*;
      end
    else $p \leftarrow (s \textbf{ mod } prim\_prime) + prim\_base$;   { we start searching here }
    end
  else begin $j \leftarrow str\_start\_macro(s)$;
    if $s = str\_ptr$ **then** $l \leftarrow cur\_length$
    else $l \leftarrow length(s)$;
    ⟨Compute the primitive code *h* 291⟩;
    $p \leftarrow h + prim\_base$;   { we start searching here; note that $0 \leq h < prim\_prime$ }
    end;
  loop begin if $prim\_text(p) > 1 + biggest\_char$ **then**   { *p* points a multi-letter primitive }
    begin if $length(prim\_text(p) - 1) = l$ **then**
      if $str\_eq\_str(prim\_text(p) - 1, s)$ **then goto** *found*;
    end
    else if $prim\_text(p) = 1 + s$ **then goto** *found*;   { *p* points a single-letter primitive }
    if $prim\_next(p) = 0$ **then**
      begin if *no_new_control_sequence* **then** $p \leftarrow undefined\_primitive$
      else ⟨Insert a new primitive after *p*, then make *p* point to it 290⟩;
      goto *found*;
      end;
    $p \leftarrow prim\_next(p)$;
    end;
found: $prim\_lookup \leftarrow p$;
  end;

290.   ⟨Insert a new primitive after *p*, then make *p* point to it 290⟩ ≡
  begin if $prim\_text(p) > 0$ **then**
    begin repeat if *prim_is_full* **then** *overflow*("primitive␣size", *prim_size*);
      decr(*prim_used*);
    until $prim\_text(prim\_used) = 0$;   { search for an empty location in *prim* }
    $prim\_next(p) \leftarrow prim\_used$; $p \leftarrow prim\_used$;
    end;
  $prim\_text(p) \leftarrow s + 1$;
  end
This code is used in section 289.

291. The value of *prim_prime* should be roughly 85% of *prim_size*, and it should be a prime number.

⟨Compute the primitive code *h* 291⟩ ≡
   $h \leftarrow str\_pool[j]$;
   for $k \leftarrow j + 1$ **to** $j + l - 1$ **do**
      begin $h \leftarrow h + h + str\_pool[k]$;
      while $h \geq prim\_prime$ **do** $h \leftarrow h - prim\_prime$;
      end

This code is used in section 289.

292. Single-character control sequences do not need to be looked up in a hash table, since we can use the character code itself as a direct address. The procedure *print_cs* prints the name of a control sequence, given a pointer to its address in *eqtb*. A space is printed after the name unless it is a single nonletter or an active character. This procedure might be invoked with invalid data, so it is "extra robust." The individual characters must be printed one at a time using *print*, since they may be unprintable.

⟨Basic printing procedures 57⟩ +≡
procedure *print_cs*(*p* : *integer*);   { prints a purported control sequence }
   begin if $p < hash\_base$ **then**   { single character }
      if $p \geq single\_base$ **then**
         if $p = null\_cs$ **then**
            begin *print_esc*("csname"); *print_esc*("endcsname"); *print_char*("␣");
            end
         else begin *print_esc*($p - single\_base$);
            if $cat\_code(p - single\_base) = letter$ **then** *print_char*("␣");
            end
      else if $p < active\_base$ **then** *print_esc*("IMPOSSIBLE.")
         else *print_char*($p - active\_base$)
   else if $p \geq undefined\_control\_sequence$ **then** *print_esc*("IMPOSSIBLE.")
      else if $(text(p) < 0) \vee (text(p) \geq str\_ptr)$ **then** *print_esc*("NONEXISTENT.")
         else begin if $(p \geq prim\_eqtb\_base) \wedge (p < frozen\_null\_font)$ **then**
               print_esc($prim\_text(p - prim\_eqtb\_base) - 1$)
            else *print_esc*($text(p)$);
            print_char("␣");
            end;
   end;

293. Here is a similar procedure; it avoids the error checks, and it never prints a space after the control sequence.

⟨Basic printing procedures 57⟩ +≡
procedure *sprint_cs*(*p* : *pointer*);   { prints a control sequence }
   begin if $p < hash\_base$ **then**
      if $p < single\_base$ **then** *print_char*($p - active\_base$)
      else if $p < null\_cs$ **then** *print_esc*($p - single\_base$)
         else begin *print_esc*("csname"); *print_esc*("endcsname");
            end
   else if $(p \geq prim\_eqtb\_base) \wedge (p < frozen\_null\_font)$ **then** *print_esc*($prim\_text(p - prim\_eqtb\_base) - 1$)
      else *print_esc*($text(p)$);
   end;

294.   We need to put TEX's "primitive" control sequences into the hash table, together with their command code (which will be the *eq_type*) and an operand (which will be the *equiv*). The *primitive* procedure does this, in a way that no TEX user can. The global value *cur_val* contains the new *eqtb* pointer after *primitive* has acted.

init procedure *primitive*(*s* : *str_number*; *c* : *quarterword*; *o* : *halfword*);
var *k*: *pool_pointer*;   { index into *str_pool* }
  j: 0 . . *buf_size*;   { index into *buffer* }
  l: *small_number*;   { length of the string }
  prim_val: *integer*;   { needed to fill *prim_eqtb* }
begin if *s* < 256 **then**
    begin *cur_val* ← *s* + *single_base*; *prim_val* ← *prim_lookup*(*s*);
    end
else begin *k* ← *str_start_macro*(*s*); *l* ← *str_start_macro*(*s* + 1) − *k*;
        { we will move *s* into the (possibly non-empty) *buffer* }
    if *first* + *l* > *buf_size* + 1 **then** *overflow*("buffer␣size", *buf_size*);
    for *j* ← 0 **to** *l* − 1 **do** *buffer*[*first* + *j*] ← *so*(*str_pool*[*k* + *j*]);
    cur_val ← *id_lookup*(*first*, *l*);   { *no_new_control_sequence* is *false* }
    flush_string; *text*(*cur_val*) ← *s*;   { we don't want to have the string twice }
    prim_val ← *prim_lookup*(*s*);
    end;
  eq_level(*cur_val*) ← *level_one*; *eq_type*(*cur_val*) ← *c*; *equiv*(*cur_val*) ← *o*;
  prim_eq_level(*prim_val*) ← *level_one*; *prim_eq_type*(*prim_val*) ← *c*; *prim_equiv*(*prim_val*) ← *o*;
  end;
tini

295.   Many of T$_{\text{E}}$X's primitives need no *equiv*, since they are identifiable by their *eq_type* alone. These primitives are loaded into the hash table as follows:

⟨ Put each of T$_{\text{E}}$X's primitives into the hash table 252 ⟩ +≡

297.   We will deal with the other primitives later, at some point in the program where their *eq_type* and *equiv* values are more meaningful. For example, the primitives for math mode will be loaded when we consider the routines that deal with formulas. It is easy to find where each particular primitive was treated by looking in the index at the end; for example, the section where "radical" entered *eqtb* is listed under '\radical primitive'. (Primitives consisting of a single nonalphabetic character, like '\/', are listed under 'Single-character primitives'.)

Meanwhile, this is a convenient place to catch up on something we were unable to do before the hash table was defined:

⟨ Print the font identifier for *font*(*p*) 297 ⟩ ≡
  print_esc(*font_id_text*(*font*(*p*)))

This code is used in sections 200 and 202.

298.   Saving and restoring equivalents.   The nested structure provided by '{...}' groups in T$_E$X means that *eqtb* entries valid in outer groups should be saved and restored later if they are overridden inside the braces. When a new *eqtb* value is being assigned, the program therefore checks to see if the previous entry belongs to an outer level. In such a case, the old value is placed on the *save_stack* just before the new value enters *eqtb*. At the end of a grouping level, i.e., when the right brace is sensed, the *save_stack* is used to restore the outer values, and the inner ones are destroyed.

Entries on the *save_stack* are of type *memory_word*. The top item on this stack is *save_stack*[p], where $p = save\_ptr - 1$; it contains three fields called *save_type*, *save_level*, and *save_index*, and it is interpreted in one of five ways:

1) If *save_type*(p) = *restore_old_value*, then *save_index*(p) is a location in *eqtb* whose current value should be destroyed at the end of the current group and replaced by *save_stack*[$p - 1$]. Furthermore if *save_index*(p) ≥ *int_base*, then *save_level*(p) should replace the corresponding entry in *xeq_level*.

2) If *save_type*(p) = *restore_zero*, then *save_index*(p) is a location in *eqtb* whose current value should be destroyed at the end of the current group, when it should be replaced by the value of *eqtb*[*undefined_control_sequence*].

3) If *save_type*(p) = *insert_token*, then *save_index*(p) is a token that should be inserted into T$_E$X's input when the current group ends.

4) If *save_type*(p) = *level_boundary*, then *save_level*(p) is a code explaining what kind of group we were previously in, and *save_index*(p) points to the level boundary word at the bottom of the entries for that group. Furthermore, in extended ε-T$_E$X mode, *save_stack*[$p - 1$] contains the source line number at which the current level of grouping was entered.

5) If *save_type*(p) = *restore_sa*, then *sa_chain* points to a chain of sparse array entries to be restored at the end of the current group. Furthermore *save_index*(p) and *save_level*(p) should replace the values of *sa_chain* and *sa_level* respectively.

   define *save_type*(#) ≡ *save_stack*[#].*hh.b0*   { classifies a *save_stack* entry }
   define *save_level*(#) ≡ *save_stack*[#].*hh.b1*   { saved level for regions 5 and 6, or group code }
   define *save_index*(#) ≡ *save_stack*[#].*hh.rh*   { *eqtb* location or token or *save_stack* location }
   define *restore_old_value* = 0   { *save_type* when a value should be restored later }
   define *restore_zero* = 1   { *save_type* when an undefined entry should be restored }
   define *insert_token* = 2   { *save_type* when a token is being saved for later use }
   define *level_boundary* = 3   { *save_type* corresponding to beginning of group }
   define *restore_sa* = 4   { *save_type* when sparse array entries should be restored }

⟨ Declare ε-T$_E$X procedures for tracing and input 314 ⟩

299.   Here are the group codes that are used to discriminate between different kinds of groups. They allow
TEX to decide what special actions, if any, should be performed when a group ends.

   Some groups are not supposed to be ended by right braces. For example, the '$' that begins a math
formula causes a *math_shift_group* to be started, and this should be terminated by a matching '$'. Similarly,
a group that starts with \left should end with \right, and one that starts with \begingroup should end
with \endgroup.

   define *bottom_level* = 0   { group code for the outside world }
   define *simple_group* = 1   { group code for local structure only }
   define *hbox_group* = 2   { code for '\hbox{...}' }
   define *adjusted_hbox_group* = 3   { code for '\hbox{...}' in vertical mode }
   define *vbox_group* = 4   { code for '\vbox{...}' }
   define *vtop_group* = 5   { code for '\vtop{...}' }
   define *align_group* = 6   { code for '\halign{...}', '\valign{...}' }
   define *no_align_group* = 7   { code for '\noalign{...}' }
   define *output_group* = 8   { code for output routine }
   define *math_group* = 9   { code for, e.g., '^{...}' }
   define *disc_group* = 10   { code for '\discretionary{...}{...}{...}' }
   define *insert_group* = 11   { code for '\insert{...}', '\vadjust{...}' }
   define *vcenter_group* = 12   { code for '\vcenter{...}' }
   define *math_choice_group* = 13   { code for '\mathchoice{...}{...}{...}{...}' }
   define *semi_simple_group* = 14   { code for '\begingroup...\endgroup' }
   define *math_shift_group* = 15   { code for '$...$' }
   define *math_left_group* = 16   { code for '\left...\right' }
   define *max_group_code* = 16

⟨ Types in the outer block 18 ⟩ +≡
   group_code = 0 . . *max_group_code*;   { *save_level* for a level boundary }

300.   The global variable *cur_group* keeps track of what sort of group we are currently in. Another global
variable, *cur_boundary*, points to the topmost *level_boundary* word. And *cur_level* is the current depth of
nesting. The routines are designed to preserve the condition that no entry in the *save_stack* or in *eqtb* ever
has a level greater than *cur_level*.

301.   ⟨ Global variables 13 ⟩ +≡
save_stack: **array** [0 . . *save_size*] **of** *memory_word*;
save_ptr: 0 . . *save_size*;   { first unused entry on *save_stack* }
max_save_stack: 0 . . *save_size*;   { maximum usage of save stack }
cur_level: *quarterword*;   { current nesting level for groups }
cur_group: *group_code*;   { current group type }
cur_boundary: 0 . . *save_size*;   { where the current level begins }

302.   At this time it might be a good idea for the reader to review the introduction to *eqtb* that was given
above just before the long lists of parameter names. Recall that the "outer level" of the program is *level_one*,
since undefined control sequences are assumed to be "defined" at *level_zero*.

⟨ Set initial values of key variables 23 ⟩ +≡
   save_ptr ← 0; *cur_level* ← *level_one*; *cur_group* ← *bottom_level*; *cur_boundary* ← 0; *max_save_stack* ← 0;

303. The following macro is used to test if there is room for up to seven more entries on *save_stack*. By making a conservative test like this, we can get by with testing for overflow in only a few places.

define *check_full_save_stack* ≡
        if *save_ptr* > *max_save_stack* **then**
          begin *max_save_stack* ← *save_ptr*;
          if *max_save_stack* > *save_size* − 7 **then** *overflow*("save␣size", *save_size*);
          end

304. Procedure *new_save_level* is called when a group begins. The argument is a group identification code like '*hbox_group*'. After calling this routine, it is safe to put five more entries on *save_stack*.

In some cases integer-valued items are placed onto the *save_stack* just below a *level_boundary* word, because this is a convenient place to keep information that is supposed to "pop up" just when the group has finished. For example, when '\hbox to 100pt{...}' is being treated, the 100pt dimension is stored on *save_stack* just before *new_save_level* is called.

We use the notation *saved*(k) to stand for an integer item that appears in location *save_ptr* + k of the save stack.

define *saved*(#) ≡ *save_stack*[*save_ptr* + #].*int*

procedure *new_save_level*(*c* : *group_code*);   { begin a new level of grouping }
  begin *check_full_save_stack*;
  if *eTeX_ex* **then**
    begin *saved*(0) ← *line*; *incr*(*save_ptr*);
    end;
  save_type(*save_ptr*) ← *level_boundary*; *save_level*(*save_ptr*) ← *cur_group*;
  save_index(*save_ptr*) ← *cur_boundary*;
  if *cur_level* = *max_quarterword* **then**
    overflow("grouping␣levels", *max_quarterword* − *min_quarterword*);
       { quit if (*cur_level* + 1) is too big to be stored in *eqtb* }
  cur_boundary ← *save_ptr*; *cur_group* ← *c*;
  stat if *tracing_groups* > 0 **then** *group_trace*(*false*);
  tats
  incr(*cur_level*); *incr*(*save_ptr*);
  end;

305. Just before an entry of *eqtb* is changed, the following procedure should be called to update the other data structures properly. It is important to keep in mind that reference counts in *mem* include references from within *save_stack*, so these counts must be handled carefully.

procedure *eq_destroy*(*w* : *memory_word*);   { gets ready to forget *w* }
  var *q*: *pointer*;   { equiv field of *w* }
  begin case *eq_type_field*(*w*) **of**
  call, *long_call*, *outer_call*, *long_outer_call*: *delete_token_ref*(*equiv_field*(*w*));
  glue_ref: *delete_glue_ref*(*equiv_field*(*w*));
  shape_ref: **begin** *q* ← *equiv_field*(*w*);   { we need to free a \parshape block }
    if *q* ≠ *null* **then** *free_node*(*q*, *info*(*q*) + *info*(*q*) + 1);
    end;   { such a block is $2n + 1$ words long, where $n = info(q)$ }
  box_ref: *flush_node_list*(*equiv_field*(*w*));
  ⟨ Cases for *eq_destroy* 1645 ⟩
  othercases *do_nothing*
  endcases;
  end;

306. To save a value of *eqtb*[*p*] that was established at level *l*, we can use the following subroutine.

procedure *eq_save*(*p* : *pointer*; *l* : *quarterword*);   { saves *eqtb*[*p*] }
  begin *check_full_save_stack*;
  if *l* = *level_zero* **then** *save_type*(*save_ptr*) ← *restore_zero*
  else begin *save_stack*[*save_ptr*] ← *eqtb*[*p*]; *incr*(*save_ptr*); *save_type*(*save_ptr*) ← *restore_old_value*;
    end;
  save_level(*save_ptr*) ← *l*; *save_index*(*save_ptr*) ← *p*; *incr*(*save_ptr*);
  end;

307. The procedure *eq_define* defines an *eqtb* entry having specified *eq_type* and *equiv* fields, and saves the former value if appropriate. This procedure is used only for entries in the first four regions of *eqtb*, i.e., only for entries that have *eq_type* and *equiv* fields. After calling this routine, it is safe to put four more entries on *save_stack*, provided that there was room for four more entries before the call, since *eq_save* makes the necessary test.

  define *assign_trace*(#) ≡
          stat if *tracing_assigns* > 0 **then** *restore_trace*(#);
          tats
procedure *eq_define*(*p* : *pointer*; *t* : *quarterword*; *e* : *halfword*);   { new data for *eqtb* }
  label *exit*;
  begin if *eTeX_ex* ∧ (*eq_type*(*p*) = *t*) ∧ (*equiv*(*p*) = *e*) **then**
    begin *assign_trace*(*p*, "reassigning")
    eq_destroy(*eqtb*[*p*]); **return**;
    end;
  assign_trace(*p*, "changing")
  if *eq_level*(*p*) = *cur_level* **then** *eq_destroy*(*eqtb*[*p*])
  else if *cur_level* > *level_one* **then** *eq_save*(*p*, *eq_level*(*p*));
  eq_level(*p*) ← *cur_level*; *eq_type*(*p*) ← *t*; *equiv*(*p*) ← *e*; *assign_trace*(*p*, "into")
exit: **end**;

308. The counterpart of *eq_define* for the remaining (fullword) positions in *eqtb* is called *eq_word_define*. Since *xeq_level*[*p*] ≥ *level_one* for all *p*, a 'restore_zero' will never be used in this case.

procedure *eq_word_define*(*p* : *pointer*; *w* : *integer*);
  label *exit*;
  begin if *eTeX_ex* ∧ (*eqtb*[*p*].*int* = *w*) **then**
    begin *assign_trace*(*p*, "reassigning")
    return;
    end;
  assign_trace(*p*, "changing")
  if *xeq_level*[*p*] ≠ *cur_level* **then**
    begin *eq_save*(*p*, *xeq_level*[*p*]); *xeq_level*[*p*] ← *cur_level*;
    end;
  eqtb[*p*].*int* ← *w*; *assign_trace*(*p*, "into")
exit: **end**;

309. The *eq_define* and *eq_word_define* routines take care of local definitions. Global definitions are done in almost the same way, but there is no need to save old values, and the new value is associated with *level_one*.

procedure *geq_define*(*p* : *pointer*; *t* : *quarterword*; *e* : *halfword*);   { global *eq_define* }
  begin *assign_trace*(*p*, "globally␣changing")
  begin *eq_destroy*(*eqtb*[*p*]); *eq_level*(*p*) ← *level_one*; *eq_type*(*p*) ← *t*; *equiv*(*p*) ← *e*;
  end; *assign_trace*(*p*, "into")
  end;

procedure *geq_word_define*(*p* : *pointer*; *w* : *integer*);   { global *eq_word_define* }
  begin *assign_trace*(*p*, "globally␣changing")
  begin *eqtb*[*p*].*int* ← *w*; *xeq_level*[*p*] ← *level_one*;
  end; *assign_trace*(*p*, "into")
  end;

310. Subroutine *save_for_after* puts a token on the stack for save-keeping.

procedure *save_for_after*(*t* : *halfword*);
  begin if *cur_level* > *level_one* **then**
    begin *check_full_save_stack*; *save_type*(*save_ptr*) ← *insert_token*; *save_level*(*save_ptr*) ← *level_zero*;
    save_index(*save_ptr*) ← *t*; *incr*(*save_ptr*);
    end;
  end;

311. The *unsave* routine goes the other way, taking items off of *save_stack*. This routine takes care of restoration when a level ends; everything belonging to the topmost group is cleared off of the save stack.

procedure *back_input*; *forward*;
procedure *unsave*;   { pops the top level off the save stack }
  label *done*;
  var *p*: *pointer*;   { position to be restored }
    l: *quarterword*;   { saved level, if in fullword regions of *eqtb* }
    t: *halfword*;   { saved value of *cur_tok* }
    a: *boolean*;   { have we already processed an \aftergroup ? }
  begin *a* ← *false*;
  if *cur_level* > *level_one* **then**
    begin *decr*(*cur_level*); ⟨ Clear off top level from *save_stack* 312 ⟩;
    end
  else *confusion*("curlevel");   { *unsave* is not used when *cur_group* = *bottom_level* }
  end;

312. ⟨Clear off top level from *save_stack* 312⟩ ≡

loop begin *decr*(*save_ptr*);
  if *save_type*(*save_ptr*) = *level_boundary* **then goto** *done*;
  p ← *save_index*(*save_ptr*);
  if *save_type*(*save_ptr*) = *insert_token* **then** ⟨Insert token *p* into TEX's input 356⟩
  else if *save_type*(*save_ptr*) = *restore_sa* **then**
      begin *sa_restore*; *sa_chain* ← *p*; *sa_level* ← *save_level*(*save_ptr*);
      end
    else begin if *save_type*(*save_ptr*) = *restore_old_value* **then**
        begin *l* ← *save_level*(*save_ptr*); *decr*(*save_ptr*);
        end
      else *save_stack*[*save_ptr*] ← *eqtb*[*undefined_control_sequence*];
      ⟨Store *save_stack*[*save_ptr*] in *eqtb*[*p*], unless *eqtb*[*p*] holds a global value 313⟩;
      end;
    end;
done: **stat if** *tracing_groups* > 0 **then** *group_trace*(*true*);
  tats
  if *grp_stack*[*in_open*] = *cur_boundary* **then** *group_warning*;
        { groups possibly not properly nested with files }
  cur_group ← *save_level*(*save_ptr*); *cur_boundary* ← *save_index*(*save_ptr*);
  if *eTeX_ex* **then** *decr*(*save_ptr*)

This code is used in section 311.

313. A global definition, which sets the level to *level_one*, will not be undone by *unsave*. If at least one global definition of *eqtb*[*p*] has been carried out within the group that just ended, the last such definition will therefore survive.

⟨Store *save_stack*[*save_ptr*] in *eqtb*[*p*], unless *eqtb*[*p*] holds a global value 313⟩ ≡

if *p* < *int_base* **then**
    if *eq_level*(*p*) = *level_one* **then**
      begin *eq_destroy*(*save_stack*[*save_ptr*]);   { destroy the saved value }
      stat if *tracing_restores* > 0 **then** *restore_trace*(*p*, "retaining");
      tats
      end
    else begin *eq_destroy*(*eqtb*[*p*]);   { destroy the current value }
      eqtb[*p*] ← *save_stack*[*save_ptr*];   { restore the saved value }
      stat if *tracing_restores* > 0 **then** *restore_trace*(*p*, "restoring");
      tats
      end
  else if *xeq_level*[*p*] ≠ *level_one* **then**
      begin *eqtb*[*p*] ← *save_stack*[*save_ptr*]; *xeq_level*[*p*] ← *l*;
      stat if *tracing_restores* > 0 **then** *restore_trace*(*p*, "restoring");
      tats
      end
    else begin stat if *tracing_restores* > 0 **then** *restore_trace*(*p*, "retaining");
      tats
      end

This code is used in section 312.

314.   ⟨Declare ε-T$_{\text{E}}$X procedures for tracing and input 314⟩ ≡
   stat procedure *restore_trace*(p : *pointer*; s : *str_number*);   { *eqtb*[p] has just been restored or retained }
   begin *begin_diagnostic*; *print_char*("{"); *print*(s); *print_char*("␣"); *show_eqtb*(p); *print_char*("}");
   end_diagnostic(*false*);
   end;
   tats

See also sections 1471, 1472, 1567, 1568, 1585, 1587, 1588, 1632, 1634, 1648, 1649, 1650, 1651, and 1652.

This code is used in section 298.

315.   When looking for possible pointers to a memory location, it is helpful to look for references from *eqtb* that might be waiting on the save stack. Of course, we might find spurious pointers too; but this routine is merely an aid when debugging, and at such times we are grateful for any scraps of information, even if they prove to be irrelevant.

⟨Search *save_stack* for equivalents that point to p 315⟩ ≡
   if *save_ptr* > 0 **then**
     for $q \leftarrow 0$ **to** *save_ptr* − 1 **do**
       begin if *equiv_field*(*save_stack*[q]) = p **then**
         begin *print_nl*("SAVE("); *print_int*(q); *print_char*(")");
         end;
       end

This code is used in section 197.

316.   Most of the parameters kept in *eqtb* can be changed freely, but there's an exception: The magnification should not be used with two different values during any T$_{\text{E}}$X job, since a single magnification is applied to an entire run. The global variable *mag_set* is set to the current magnification whenever it becomes necessary to "freeze" it at a particular value.

⟨Global variables 13⟩ +≡
mag_set: *integer*;   { if nonzero, this magnification should be used henceforth }

317.   ⟨Set initial values of key variables 23⟩ +≡
   mag_set ← 0;

318.   The *prepare_mag* subroutine is called whenever T$_{\text{E}}$X wants to use *mag* for magnification.

procedure *prepare_mag*;
   begin if (*mag_set* > 0) ∧ (*mag* ≠ *mag_set*) **then**
     begin *print_err*("Incompatible␣magnification␣("); *print_int*(*mag*); *print*(");");
     print_nl("␣the␣previous␣value␣will␣be␣retained");
     help2("I␣can␣handle␣only␣one␣magnification␣ratio␣per␣job.␣So␣I´ve")
     ("reverted␣to␣the␣magnification␣you␣used␣earlier␣on␣this␣run.");
     int_error(*mag_set*); *geq_word_define*(*int_base* + *mag_code*, *mag_set*);   { *mag* ← *mag_set* }
     end;
   if (*mag* ≤ 0) ∨ (*mag* > 32768) **then**
     begin *print_err*("Illegal␣magnification␣has␣been␣changed␣to␣1000");
     help1("The␣magnification␣ratio␣must␣be␣between␣1␣and␣32768."); *int_error*(*mag*);
     geq_word_define(*int_base* + *mag_code*, 1000);
     end;
   mag_set ← *mag*;
   end;

319.   Token lists.   A TEX token is either a character or a control sequence, and it is represented internally in one of two ways: (1) A character whose ASCII code number is c and whose command code is m is represented as the number $2^{21}m + c$; the command code is in the range $1 \leq m \leq 14$. (2) A control sequence whose *eqtb* address is p is represented as the number $cs\_token\_flag + p$. Here $cs\_token\_flag = 2^{25} - 1$ is larger than $2^{21}m + c$, yet it is small enough that $cs\_token\_flag + p < max\_halfword$; thus, a token fits comfortably in a halfword.

A token t represents a *left_brace* command if and only if $t < left\_brace\_limit$; it represents a *right_brace* command if and only if we have $left\_brace\_limit \leq t < right\_brace\_limit$; and it represents a *match* or *end_match* command if and only if $match\_token \leq t \leq end\_match\_token$. The following definitions take care of these token-oriented constants and a few others.

> **define** $cs\_token\_flag = \texttt{"1FFFFFF}$ { amount added to the *eqtb* location in a token that stands for a
> control sequence; is a multiple of $\texttt{"10000}$, less 1 }
> **define** $max\_char\_val = \texttt{"200000}$ { to separate char and command code }
> **define** $left\_brace\_token = \texttt{"200000}$ { $2^{21} \cdot left\_brace$ }
> **define** $left\_brace\_limit = \texttt{"400000}$ { $2^{21} \cdot (left\_brace + 1)$ }
> **define** $right\_brace\_token = \texttt{"400000}$ { $2^{21} \cdot right\_brace$ }
> **define** $right\_brace\_limit = \texttt{"600000}$ { $2^{21} \cdot (right\_brace + 1)$ }
> **define** $math\_shift\_token = \texttt{"600000}$ { $2^{21} \cdot math\_shift$ }
> **define** $tab\_token = \texttt{"800000}$ { $2^{21} \cdot tab\_mark$ }
> **define** $out\_param\_token = \texttt{"A00000}$ { $2^{21} \cdot out\_param$ }
> **define** $space\_token = \texttt{"1400020}$ { $2^{21} \cdot spacer + \texttt{"}\textvisiblespace\texttt{"}$ }
> **define** $letter\_token = \texttt{"1600000}$ { $2^{21} \cdot letter$ }
> **define** $other\_token = \texttt{"1800000}$ { $2^{21} \cdot other\_char$ }
> **define** $match\_token = \texttt{"1A00000}$ { $2^{21} \cdot match$ }
> **define** $end\_match\_token = \texttt{"1C00000}$ { $2^{21} \cdot end\_match$ }
>
> **define** $protected\_token = end\_match\_token + 1$ { $2^{21} \cdot end\_match + 1$ }

320.   ⟨ Check the "constant" values for consistency 14 ⟩ +≡
> **if** $cs\_token\_flag + undefined\_control\_sequence > max\_halfword$ **then** $bad \leftarrow 21$;

321.   A token list is a singly linked list of one-word nodes in *mem*, where each word contains a token and a link. Macro definitions, output-routine definitions, marks, \write texts, and a few other things are remembered by TEX in the form of token lists, usually preceded by a node with a reference count in its *token_ref_count* field. The token stored in location p is called *info*(p).

Three special commands appear in the token lists of macro definitions. When $m = match$, it means that TEX should scan a parameter for the current macro; when $m = end\_match$, it means that parameter matching should end and TEX should start reading the macro text; and when $m = out\_param$, it means that TEX should insert parameter number c into the text at this point.

The enclosing { and } characters of a macro definition are omitted, but an output routine will be enclosed in braces.

Here is an example macro definition that illustrates these conventions. After TEX processes the text

$$\text{\def\mac a\#1\#2 \b \{\#1\-a \#\#1\#2 \#2\}}$$

the definition of \mac is represented as a token list containing

> (reference count), *letter* a, *match* #, *match* #, *spacer* ␣, \b, *end_match*,
> *out_param* 1, \-, *letter* a, *spacer* ␣, *mac_param* #, *other_char* 1,
> *out_param* 2, *spacer* ␣, *out_param* 2.

The procedure *scan_toks* builds such token lists, and *macro_call* does the parameter matching.

Examples such as
$$\text{\def\m\{\def\m\{a\}␣b\}}$$

explain why reference counts would be needed even if TEX had no \let operation: When the token list for \m is being read, the redefinition of \m changes the *eqtb* entry before the token list has been fully consumed, so we dare not simply destroy a token list when its control sequence is being redefined.

If the parameter-matching part of a definition ends with '#{', the corresponding token list will have '{' just before the '*end_match*' and also at the very end. The first '{' is used to delimit the parameter; the second one keeps the first from disappearing.

322. The procedure *show_token_list*, which prints a symbolic form of the token list that starts at a given node p, illustrates these conventions. The token list being displayed should not begin with a reference count. However, the procedure is intended to be robust, so that if the memory links are awry or if p is not really a pointer to a token list, nothing catastrophic will happen.

An additional parameter q is also given; this parameter is either null or it points to a node in the token list where a certain magic computation takes place that will be explained later. (Basically, q is non-null when we are printing the two-line context information at the time of an error message; q marks the place corresponding to where the second line should begin.)

For example, if p points to the node containing the first a in the token list above, then *show_token_list* will print the string

$$\text{`a\#1\#2}_{\sqcup}\text{\textbackslash b}_{\sqcup}\text{->\#1\textbackslash -a}_{\sqcup}\text{\#\#1\#2}_{\sqcup}\text{\#2'};$$

and if q points to the node containing the second a, the magic computation will be performed just before the second a is printed.

The generation will stop, and '\ETC.' will be printed, if the length of printing exceeds a given limit l. Anomalous entries are printed in the form of control sequences that are not followed by a blank space, e.g., '\BAD.'; this cannot be confused with actual control sequences because a real control sequence named BAD would come out '\BAD$_{\sqcup}$'.

⟨ Declare the procedure called *show_token_list* 322 ⟩ ≡
procedure *show_token_list*(*p, q* : *integer*; *l* : *integer*);
   label *exit*;
   var *m, c*: *integer*;   { pieces of a token }
      match_chr: *integer*;   { character used in a '*match*' }
      n: *ASCII_code*;   { the highest parameter number, as an ASCII digit }
   begin *match_chr* ← "#"; *n* ← "0"; *tally* ← 0;
   while (*p* ≠ *null*) ∧ (*tally* < *l*) **do**
      begin if *p* = *q* **then** ⟨ Do magic computation 350 ⟩;
      ⟨ Display token *p*, and **return** if there are problems 323 ⟩;
      p ← *link*(*p*);
      end;
   if *p* ≠ *null* **then** *print_esc*("ETC.");
exit: **end**;

This code is used in section 141.

323. ⟨ Display token *p*, and **return** if there are problems 323 ⟩ ≡
   if (*p* < *hi_mem_min*) ∨ (*p* > *mem_end*) **then**
      begin *print_esc*("CLOBBERED."); **return**;
      end;
   if *info*(*p*) ≥ *cs_token_flag* **then** *print_cs*(*info*(*p*) − *cs_token_flag*)
   else begin *m* ← *info*(*p*) **div** *max_char_val*; *c* ← *info*(*p*) **mod** *max_char_val*;
      if *info*(*p*) < 0 **then** *print_esc*("BAD.")
      else ⟨ Display the token (*m, c*) 324 ⟩;
      end

This code is used in section 322.

324.   The procedure usually "learns" the character code used for macro parameters by seeing one in a *match* command before it runs into any *out_param* commands.

⟨Display the token (m, c) 324⟩ ≡
  case m **of**
  left_brace, *right_brace*, *math_shift*, *tab_mark*, *sup_mark*, *sub_mark*, *spacer*, *letter*, *other_char*: *print_char*(c);
  mac_param: **begin** *print_char*(c); *print_char*(c);
    end;
  out_param: **begin** *print_char*(*match_chr*);
    if $c \leq 9$ **then** *print_char*(c + "0")
    else begin *print_char*("!"); **return**;
      end;
    end;
  match: **begin** *match_chr* ← c; *print_char*(c); *incr*(n); *print_char*(n);
    if $n > $ "9" **then return**;
    end;
  end_match: **if** $c = 0$ **then** *print*("->");
    othercases *print_esc*("BAD.")
  endcases

This code is used in section 323.

325.   Here's the way we sometimes want to display a token list, given a pointer to its reference count; the pointer may be null.

procedure *token_show*(p : *pointer*);
  begin if $p \neq null$ **then** *show_token_list*(*link*(p), *null*, 10000000);
  end;

326.   The *print_meaning* subroutine displays *cur_cmd* and *cur_chr* in symbolic form, including the expansion of a macro or mark.

procedure *print_meaning*;
  begin *print_cmd_chr*(*cur_cmd*, *cur_chr*);
  if *cur_cmd* ≥ *call* **then**
    begin *print_char*(":"); *print_ln*; *token_show*(*cur_chr*);
    end
  else if (*cur_cmd* = *top_bot_mark*) ∧ (*cur_chr* < *marks_code*) **then**
      begin *print_char*(":"); *print_ln*; *token_show*(*cur_mark*[*cur_chr*]);
      end;
  end;

327. Introduction to the syntactic routines.   Let's pause a moment now and try to look at the Big Picture. The TeX program consists of three main parts: syntactic routines, semantic routines, and output routines. The chief purpose of the syntactic routines is to deliver the user's input to the semantic routines, one token at a time. The semantic routines act as an interpreter responding to these tokens, which may be regarded as commands. And the output routines are periodically called on to convert box-and-glue lists into a compact set of instructions that will be sent to a typesetter. We have discussed the basic data structures and utility routines of TeX, so we are good and ready to plunge into the real activity by considering the syntactic routines.

Our current goal is to come to grips with the *get_next* procedure, which is the keystone of TeX's input mechanism. Each call of *get_next* sets the value of three variables *cur_cmd*, *cur_chr*, and *cur_cs*, representing the next input token.

> *cur_cmd* denotes a command code from the long list of codes given above;
> *cur_chr* denotes a character code or other modifier of the command code;
> *cur_cs* is the *eqtb* location of the current control sequence,
>   if the current token was a control sequence, otherwise it's zero.

Underlying this external behavior of *get_next* is all the machinery necessary to convert from character files to tokens. At a given time we may be only partially finished with the reading of several files (for which \input was specified), and partially finished with the expansion of some user-defined macros and/or some macro parameters, and partially finished with the generation of some text in a template for \halign, and so on. When reading a character file, special characters must be classified as math delimiters, etc.; comments and extra blank spaces must be removed, paragraphs must be recognized, and control sequences must be found in the hash table. Furthermore there are occasions in which the scanning routines have looked ahead for a word like 'plus' but only part of that word was found, hence a few characters must be put back into the input and scanned again.

To handle these situations, which might all be present simultaneously, TeX uses various stacks that hold information about the incomplete activities, and there is a finite state control for each level of the input mechanism. These stacks record the current state of an implicitly recursive process, but the *get_next* procedure is not recursive. Therefore it will not be difficult to translate these algorithms into low-level languages that do not support recursion.

⟨ Global variables 13 ⟩ +≡
cur_cmd: *eight_bits*;   { current command set by *get_next* }
cur_chr: *halfword*;   { operand of current command }
cur_cs: *pointer*;   { control sequence found here, zero if none found }
cur_tok: *halfword*;   { packed representative of *cur_cmd* and *cur_chr* }

328. The *print_cmd_chr* routine prints a symbolic interpretation of a command code and its modifier. This is used in certain 'You can´t' error messages, and in the implementation of diagnostic routines like \show.

The body of *print_cmd_chr* is a rather tedious listing of print commands, and most of it is essentially an inverse to the *primitive* routine that enters a TEX primitive into *eqtb*. Therefore much of this procedure appears elsewhere in the program, together with the corresponding *primitive* calls.

> **define** *chr_cmd*(#) ≡
>   **begin** *print*(#);
>   **if** *chr_code* < ″10000 **then** *print_ASCII*(*chr_code*)
>   **else** *print_char*(*chr_code*);   {non-Plane 0 Unicodes can't be sent through *print_ASCII*}
>   **end**

⟨Declare the procedure called *print_cmd_chr* 328⟩ ≡
procedure *print_cmd_chr*(*cmd* : *quarterword*; *chr_code* : *halfword*);
  var *n*: *integer*;   {temp variable}
    font_name_str: *str_number*;   {local vars for \fontname quoting extension}
    quote_char: *UTF16_code*;
  begin case *cmd* **of**
  left_brace: *chr_cmd*("begin-group␣character␣");
  right_brace: *chr_cmd*("end-group␣character␣");
  math_shift: *chr_cmd*("math␣shift␣character␣");
  mac_param: *chr_cmd*("macro␣parameter␣character␣");
  sup_mark: *chr_cmd*("superscript␣character␣");
  sub_mark: *chr_cmd*("subscript␣character␣");
  endv: *print*("end␣of␣alignment␣template");
  spacer: *chr_cmd*("blank␣space␣");
  letter: *chr_cmd*("the␣letter␣");
  other_char: *chr_cmd*("the␣character␣");
  ⟨Cases of *print_cmd_chr* for symbolic printing of primitives 253⟩
  othercases *print*("[unknown␣command␣code!]")
  endcases;
  end;

See also section 1457.

This code is used in section 278.

329.   Here is a procedure that displays the current command.

procedure *show_cur_cmd_chr*;
  var *n*: *integer*;   { level of \if...\fi nesting }
    l: *integer*;   { line where \if started }
    p: *pointer*;
  begin *begin_diagnostic*; *print_nl*("{");
  if *mode* ≠ *shown_mode* **then**
    begin *print_mode*(*mode*); *print*(": "); *shown_mode* ← *mode*;
    end;
  print_cmd_chr(*cur_cmd*, *cur_chr*);
  if *tracing_ifs* > 0 **then**
    if *cur_cmd* ≥ *if_test* **then**
      if *cur_cmd* ≤ *fi_or_else* **then**
        begin *print*(": ");
        if *cur_cmd* = *fi_or_else* **then**
          begin *print_cmd_chr*(*if_test*, *cur_if*); *print_char*(" "); *n* ← 0; *l* ← *if_line*;
          end
        else begin *n* ← 1; *l* ← *line*;
          end;
        p ← *cond_ptr*;
        while *p* ≠ *null* **do**
          begin *incr*(*n*); *p* ← *link*(*p*);
          end;
        print("(level "); *print_int*(*n*); *print_char*(")"); *print_if_line*(*l*);
        end;
  print_char("}"); *end_diagnostic*(*false*);
  end;

330.   Input stacks and states.   This implementation of TEX uses two different conventions for representing sequential stacks.

1) If there is frequent access to the top entry, and if the stack is essentially never empty, then the top entry is kept in a global variable (even better would be a machine register), and the other entries appear in the array $stack[0 . . (ptr - 1)]$. For example, the semantic stack described above is handled this way, and so is the input stack that we are about to study.

2) If there is infrequent top access, the entire stack contents are in the array $stack[0 . . (ptr - 1)]$. For example, the $save\_stack$ is treated this way, as we have seen.

The state of TEX's input mechanism appears in the input stack, whose entries are records with six fields, called $state$, $index$, $start$, loc, $limit$, and $name$. This stack is maintained with convention (1), so it is declared in the following way:

⟨ Types in the outer block 18 ⟩ +≡
  $in\_state\_record =$ **record** $state\_field$, $index\_field$: $quarterword$;
    $start\_field$, loc_field, $limit\_field$, $name\_field$: $halfword$;
    end;

331.   ⟨ Global variables 13 ⟩ +≡
$input\_stack$: **array** $[0 . . stack\_size]$ **of** in_state_record;
$input\_ptr$: $0 . . stack\_size$;   { first unused location of $input\_stack$ }
max_in_stack: $0 . . stack\_size$;   { largest value of $input\_ptr$ when pushing }
cur_input: in_state_record;   { the "top" input state, according to convention (1) }

332.   We've already defined the special variable $loc \equiv cur\_input.loc\_field$ in our discussion of basic input-output routines. The other components of cur_input are defined in the same way:

  define $state \equiv cur\_input.state\_field$ { current scanner state }
  define $index \equiv cur\_input.index\_field$ { reference for buffer information }
  define $start \equiv cur\_input.start\_field$ { starting position in $buffer$ }
  define $limit \equiv cur\_input.limit\_field$ { end of current line in $buffer$ }
  define $name \equiv cur\_input.name\_field$ { name of the current file }

333.   Let's look more closely now at the control variables (*state*, *index*, *start*, *loc*, *limit*, *name*), assuming that TEX is reading a line of characters that have been input from some file or from the user's terminal. There is an array called *buffer* that acts as a stack of all lines of characters that are currently being read from files, including all lines on subsidiary levels of the input stack that are not yet completed. TEX will return to the other lines when it is finished with the present input file.

(Incidentally, on a machine with byte-oriented addressing, it might be appropriate to combine *buffer* with the *str_pool* array, letting the buffer entries grow downward from the top of the string pool and checking that these two tables don't bump into each other.)

The line we are currently working on begins in position *start* of the buffer; the next character we are about to read is *buffer*[*loc*]; and *limit* is the location of the last character present. If *loc* > *limit*, the line has been completely read. Usually *buffer*[*limit*] is the *end_line_char*, denoting the end of a line, but this is not true if the current line is an insertion that was entered on the user's terminal in response to an error message.

The *name* variable is a string number that designates the name of the current file, if we are reading a text file. It is zero if we are reading from the terminal; it is $n + 1$ if we are reading from input stream n, where $0 \leq n \leq 16$. (Input stream 16 stands for an invalid stream number; in such cases the input is actually from the terminal, under control of the procedure *read_toks*.) Finally $18 \leq name \leq 19$ indicates that we are reading a pseudo file created by the \scantokens command.

The *state* variable has one of three values, when we are scanning such files:

> 1) *state* = *mid_line* is the normal state.
>
> 2) *state* = *skip_blanks* is like *mid_line*, but blanks are ignored.
>
> 3) *state* = *new_line* is the state at the beginning of a line.

These state values are assigned numeric codes so that if we add the state code to the next character's command code, we get distinct values. For example, '*mid_line* + *spacer*' stands for the case that a blank space character occurs in the middle of a line when it is not being ignored; after this case is processed, the next value of *state* will be *skip_blanks*.

define *mid_line* = 1   { *state* code when scanning a line of characters }
define *skip_blanks* = 2 + *max_char_code*   { *state* code when ignoring blanks }
define *new_line* = 3 + *max_char_code* + *max_char_code*   { *state* code at start of line }

334.   Additional information about the current line is available via the *index* variable, which counts how many lines of characters are present in the buffer below the current level. We have $index = 0$ when reading from the terminal and prompting the user for each line; then if the user types, e.g., '`\input paper`', we will have $index = 1$ while reading the file `paper.tex`. However, it does not follow that *index* is the same as the input stack pointer, since many of the levels on the input stack may come from token lists. For example, the instruction '`\input paper`' might occur in a token list.

The global variable *in_open* is equal to the *index* value of the highest non-token-list level. Thus, the number of partially read lines in the buffer is $in\_open + 1$, and we have $in\_open = index$ when we are not reading a token list.

If we are not currently reading from the terminal, or from an input stream, we are reading from the file variable *input_file*[*index*]. We use the notation *terminal_input* as a convenient abbreviation for $name = 0$, and *cur_file* as an abbreviation for *input_file*[*index*].

The global variable *line* contains the line number in the topmost open file, for use in error messages. If we are not reading from the terminal, *line_stack*[*index*] holds the line number for the enclosing level, so that *line* can be restored when the current file has been read. Line numbers should never be negative, since the negative of the current line number is used to identify the user's output routine in the *mode_line* field of the semantic nest entries.

If more information about the input state is needed, it can be included in small arrays like those shown here. For example, the current page or segment number in the input file might be put into a variable *page*, maintained for enclosing levels in '*page_stack*: **array** [1 .. *max_in_open*] **of** *integer*' by analogy with *line_stack*.

> **define** *terminal_input* ≡ (*name* = 0)   { are we reading from the terminal? }
> **define** *cur_file* ≡ *input_file*[*index*]   { the current *alpha_file* variable }

⟨ Global variables 13 ⟩ +≡
in_open: 0 .. *max_in_open*;   { the number of lines in the buffer, less one }
open_parens: 0 .. *max_in_open*;   { the number of open text files }
input_file: **array** [1 .. *max_in_open*] **of** *alpha_file*;
line: *integer*;   { current line number in the current source file }
line_stack: **array** [1 .. *max_in_open*] **of** *integer*;

335.   Users of T$_{E}$X sometimes forget to balance left and right braces properly, and one of the ways T$_{E}$X tries to spot such errors is by considering an input file as broken into subfiles by control sequences that are declared to be \outer.

A variable called *scanner_status* tells T$_{E}$X whether or not to complain when a subfile ends. This variable has six possible values:

normal, means that a subfile can safely end here without incident.

skipping, means that a subfile can safely end here, but not a file, because we're reading past some conditional text that was not selected.

defining, means that a subfile shouldn't end now because a macro is being defined.

matching, means that a subfile shouldn't end now because a macro is being used and we are searching for the end of its arguments.

aligning, means that a subfile shouldn't end now because we are not finished with the preamble of an \halign or \valign.

absorbing, means that a subfile shouldn't end now because we are reading a balanced token list for \message, \write, etc.

If the *scanner_status* is not *normal*, the variable *warning_index* points to the *eqtb* location for the relevant control sequence name to print in an error message.

> **define** *skipping* $= 1$ { *scanner_status* when passing conditional text }
> **define** *defining* $= 2$ { *scanner_status* when reading a macro definition }
> **define** *matching* $= 3$ { *scanner_status* when reading macro arguments }
> **define** *aligning* $= 4$ { *scanner_status* when reading an alignment preamble }
> **define** *absorbing* $= 5$ { *scanner_status* when reading a balanced text }

⟨ Global variables 13 ⟩ $+\equiv$
scanner_status: *normal* .. *absorbing*;   { can a subfile end now? }
warning_index: *pointer*;   { identifier relevant to non-*normal* scanner status }
def_ref: *pointer*;   { reference count of token list being defined }

336.   Here is a procedure that uses *scanner_status* to print a warning message when a subfile has ended, and at certain other crucial times:

⟨ Declare the procedure called *runaway* 336 ⟩ $\equiv$
procedure *runaway*;
  var *p*: *pointer*;   { head of runaway list }
  begin if *scanner_status* > *skipping* **then**
    begin *print_nl*("Runaway␣");
    case *scanner_status* **of**
    defining: **begin** *print*("definition"); $p \leftarrow def\_ref$;
      end;
    matching: **begin** *print*("argument"); $p \leftarrow temp\_head$;
      end;
    aligning: **begin** *print*("preamble"); $p \leftarrow hold\_head$;
      end;
    absorbing: **begin** *print*("text"); $p \leftarrow def\_ref$;
      end;
    end;   { there are no other cases }
    print_char("?"); *print_ln*; *show_token_list*(*link*(*p*), *null*, *error_line* − 10);
    end;
  end;
This code is used in section 141.

337. However, all this discussion about input state really applies only to the case that we are inputting from a file. There is another important case, namely when we are currently getting input from a token list. In this case $state = token\_list$, and the conventions about the other state variables are different:

loc is a pointer to the current node in the token list, i.e., the node that will be read next. If $loc = null$, the token list has been fully read.

$start$ points to the first node of the token list; this node may or may not contain a reference count, depending on the type of token list involved.

$token\_type$, which takes the place of $index$ in the discussion above, is a code number that explains what kind of token list is being scanned.

$name$ points to the $eqtb$ address of the control sequence being expanded, if the current token list is a macro.

$param\_start$, which takes the place of $limit$, tells where the parameters of the current macro begin in the $param\_stack$, if the current token list is a macro.

The $token\_type$ can take several values, depending on where the current token list came from:

$parameter$, if a parameter is being scanned;
$u\_template$, if the $\langle u_j \rangle$ part of an alignment template is being scanned;
$v\_template$, if the $\langle v_j \rangle$ part of an alignment template is being scanned;
$backed\_up$, if the token list being scanned has been inserted as 'to be read again';
$inserted$, if the token list being scanned has been inserted as the text expansion of a `\count` or similar variable;
$macro$, if a user-defined control sequence is being scanned;
$output\_text$, if an `\output` routine is being scanned;
$every\_par\_text$, if the text of `\everypar` is being scanned;
$every\_math\_text$, if the text of `\everymath` is being scanned;
$every\_display\_text$, if the text of `\everydisplay` is being scanned;
$every\_hbox\_text$, if the text of `\everyhbox` is being scanned;
$every\_vbox\_text$, if the text of `\everyvbox` is being scanned;
$every\_job\_text$, if the text of `\everyjob` is being scanned;
$every\_cr\_text$, if the text of `\everycr` is being scanned;
$mark\_text$, if the text of a `\mark` is being scanned;
$write\_text$, if the text of a `\write` is being scanned.

The codes for $output\_text$, $every\_par\_text$, etc., are equal to a constant plus the corresponding codes for token list parameters $output\_routine\_loc$, $every\_par\_loc$, etc. The token list begins with a reference count if and only if $token\_type \geq macro$.

Since ε-TEX's additional token list parameters precede $toks\_base$, the corresponding token types must precede $write\_text$.

> **define** $token\_list = 0$ { $state$ code when scanning a token list }
> **define** $token\_type \equiv index$ { type of current token list }
> **define** $param\_start \equiv limit$ { base of macro parameters in $param\_stack$ }
> **define** $parameter = 0$ { $token\_type$ code for parameter }
> **define** $u\_template = 1$ { $token\_type$ code for $\langle u_j \rangle$ template }
> **define** $v\_template = 2$ { $token\_type$ code for $\langle v_j \rangle$ template }
> **define** $backed\_up = 3$ { $token\_type$ code for text to be reread }
> **define** $backed\_up\_char = 4$ { special code for backed-up char from X eTeXinterchartoks hook }
> **define** $inserted = 5$ { $token\_type$ code for inserted texts }
> **define** $macro = 6$ { $token\_type$ code for defined control sequences }
> **define** $output\_text = 7$ { $token\_type$ code for output routines }
> **define** $every\_par\_text = 8$ { $token\_type$ code for `\everypar` }
> **define** $every\_math\_text = 9$ { $token\_type$ code for `\everymath` }
> **define** $every\_display\_text = 10$ { $token\_type$ code for `\everydisplay` }
> **define** $every\_hbox\_text = 11$ { $token\_type$ code for `\everyhbox` }

define *every_vbox_text* = 12   { *token_type* code for \everyvbox }
define *every_job_text* = 13   { *token_type* code for \everyjob }
define *every_cr_text* = 14   { *token_type* code for \everycr }
define *mark_text* = 15   { *token_type* code for \topmark, etc. }
define *eTeX_text_offset* = *output_routine_loc* − *output_text*
define *every_eof_text* = *every_eof_loc* − *eTeX_text_offset*   { *token_type* code for \everyeof }
define *inter_char_text* = *XeTeX_inter_char_loc* − *eTeX_text_offset*
            { *token_type* code for \XeTeXinterchartoks }
define *write_text* = *toks_base* − *eTeX_text_offset*   { *token_type* code for \write }

338.   The *param_stack* is an auxiliary array used to hold pointers to the token lists for parameters at the current level and subsidiary levels of input. This stack is maintained with convention (2), and it grows at a different rate from the others.

⟨ Global variables 13 ⟩ +≡
param_stack: **array** [0 . . *param_size*] **of** *pointer*;   { token list pointers for parameters }
param_ptr: 0 . . *param_size*;   { first unused entry in *param_stack* }
max_param_stack: *integer*;   { largest value of *param_ptr*, will be ≤ *param_size* + 9 }

339.   The input routines must also interact with the processing of \halign and \valign, since the appearance of tab marks and \cr in certain places is supposed to trigger the beginning of special ⟨v_j⟩ template text in the scanner. This magic is accomplished by an *align_state* variable that is increased by 1 when a '{' is scanned and decreased by 1 when a '}' is scanned. The *align_state* is nonzero during the ⟨u_j⟩ template, after which it is set to zero; the ⟨v_j⟩ template begins when a tab mark or \cr occurs at a time that *align_state* = 0.

⟨ Global variables 13 ⟩ +≡
align_state: *integer*;   { group level with respect to current alignment }

340.   Thus, the "current input state" can be very complicated indeed; there can be many levels and each level can arise in a variety of ways. The *show_context* procedure, which is used by TEX's error-reporting routine to print out the current input state on all levels down to the most recent line of characters from an input file, illustrates most of these conventions. The global variable *base_ptr* contains the lowest level that was displayed by this procedure.

⟨ Global variables 13 ⟩ +≡
base_ptr: 0 . . *stack_size*;   { shallowest level shown by *show_context* }

341.   The status at each level is indicated by printing two lines, where the first line indicates what was read so far and the second line shows what remains to be read. The context is cropped, if necessary, so that the first line contains at most *half_error_line* characters, and the second contains at most *error_line*. Non-current input levels whose *token_type* is '*backed_up*' are shown only if they have not been fully read.

procedure *show_context*;   { prints where the scanner is }
  label *done*;
  var *old_setting*: 0 . . *max_selector*;   { saved *selector* setting }
    nn: *integer*;   { number of contexts shown so far, less one }
    bottom_line: *boolean*;   { have we reached the final context to be shown? }
    ⟨ Local variables for formatting calculations 345 ⟩
  begin *base_ptr* ← *input_ptr*; *input_stack*[*base_ptr*] ← *cur_input*;   { store current state }
  nn ← −1; *bottom_line* ← *false*;
  loop begin *cur_input* ← *input_stack*[*base_ptr*];   { enter into the context }
    if (*state* ≠ *token_list*) **then**
      if (*name* > 19) ∨ (*base_ptr* = 0) **then** *bottom_line* ← *true*;
    if (*base_ptr* = *input_ptr*) ∨ *bottom_line* ∨ (*nn* < *error_context_lines*) **then**
      ⟨ Display the current context 342 ⟩
    else if *nn* = *error_context_lines* **then**
        begin *print_nl*("..."); *incr*(*nn*);   { omitted if *error_context_lines* < 0 }
        end;
    if *bottom_line* **then goto** *done*;
    decr(*base_ptr*);
    end;
done: *cur_input* ← *input_stack*[*input_ptr*];   { restore original state }
  end;

342.   ⟨ Display the current context 342 ⟩ ≡
  begin if (*base_ptr* = *input_ptr*) ∨ (*state* ≠ *token_list*) ∨ (*token_type* ≠ *backed_up*) ∨ (*loc* ≠ *null*) **then**
        { we omit backed-up token lists that have already been read }
    begin *tally* ← 0;   { get ready to count characters }
    old_setting ← *selector*;
    if *state* ≠ *token_list* **then**
      begin ⟨ Print location of current line 343 ⟩;
      ⟨ Pseudoprint the line 348 ⟩;
      end
    else begin ⟨ Print type of token list 344 ⟩;
      ⟨ Pseudoprint the token list 349 ⟩;
      end;
    selector ← *old_setting*;   { stop pseudoprinting }
    ⟨ Print two lines using the tricky pseudoprinted information 347 ⟩;
    incr(*nn*);
    end;
  end

This code is used in section 341.

343. This routine should be changed, if necessary, to give the best possible indication of where the current line resides in the input file. For example, on some systems it is best to print both a page and line number.

⟨ Print location of current line 343 ⟩ ≡
  if $name \leq 17$ **then**
    if $terminal\_input$ **then**
      if $base\_ptr = 0$ **then** $print\_nl("<*>")$
      else $print\_nl("<insert>_{\sqcup}")$
    else begin $print\_nl("<read_{\sqcup}")$;
      if $name = 17$ **then** $print\_char("*")$ **else** $print\_int(name - 1)$;
      $print\_char(">")$;
      end
  else begin $print\_nl("l.")$;
    if $index = in\_open$ **then** $print\_int(line)$
    else $print\_int(line\_stack[index + 1])$;   { input from a pseudo file }
    end;
  $print\_char("_{\sqcup}")$
This code is used in section 342.

344. ⟨ Print type of token list 344 ⟩ ≡
  case $token\_type$ **of**
  $parameter$: $print\_nl("<argument>_{\sqcup}")$;

  othercases $print\_nl("?")$ { this should never happen }
  endcases
This code is used in section 342.

345.   Here it is necessary to explain a little trick. We don't want to store a long string that corresponds to a token list, because that string might take up lots of memory; and we are printing during a time when an error message is being given, so we dare not do anything that might overflow one of TEX's tables. So 'pseudoprinting' is the answer: We enter a mode of printing that stores characters into a buffer of length *error_line*, where character $k + 1$ is placed into *trick_buf*[k **mod** *error_line*] if $k <$ *trick_count*, otherwise character k is dropped. Initially we set *tally* $\leftarrow$ 0 and *trick_count* $\leftarrow$ 1000000; then when we reach the point where transition from line 1 to line 2 should occur, we set *first_count* $\leftarrow$ *tally* and *trick_count* $\leftarrow$ max(*error_line*, *tally* $+ 1 +$ *error_line* $-$ *half_error_line*). At the end of the pseudoprinting, the values of *first_count*, *tally*, and *trick_count* give us all the information we need to print the two lines, and all of the necessary text is in *trick_buf*.

Namely, let l be the length of the descriptive information that appears on the first line. The length of the context information gathered for that line is $k =$ *first_count*, and the length of the context information gathered for line 2 is $m =$ min(*tally*, *trick_count*) $- k$. If $l + k \leq h$, where $h =$ *half_error_line*, we print *trick_buf*[0 .. $k - 1$] after the descriptive information on line 1, and set $n \leftarrow l + k$; here n is the length of line 1. If $l + k > h$, some cropping is necessary, so we set $n \leftarrow h$ and print '...' followed by

$$trick\_buf\,[(l + k - h + 3) \mathrel{..} k - 1],$$

where subscripts of *trick_buf* are circular modulo *error_line*. The second line consists of n spaces followed by *trick_buf*[k .. $(k + m - 1)$], unless $n + m >$ *error_line*; in the latter case, further cropping is done. This is easier to program than to explain.

⟨ Local variables for formatting calculations 345 ⟩ ≡
i: 0 .. *buf_size*;   { index into *buffer* }
j: 0 .. *buf_size*;   { end of current line in *buffer* }
l: 0 .. *half_error_line*;   { length of descriptive information on line 1 }
m: *integer*;   { context information gathered for line 2 }
n: 0 .. *error_line*;   { length of line 1 }
p: *integer*;   { starting or ending place in *trick_buf* }
q: *integer*;   { temporary index }
This code is used in section 341.

346.   The following code sets up the print routines so that they will gather the desired information.

define *begin_pseudoprint* ≡
        begin $l \leftarrow$ *tally*; *tally* $\leftarrow$ 0; *selector* $\leftarrow$ *pseudo*; *trick_count* $\leftarrow$ 1000000;
        end
define *set_trick_count* ≡
        begin *first_count* $\leftarrow$ *tally*; *trick_count* $\leftarrow$ *tally* $+ 1 +$ *error_line* $-$ *half_error_line*;
        if *trick_count* $<$ *error_line* **then** *trick_count* $\leftarrow$ *error_line*;
        end

347. And the following code uses the information after it has been gathered.

⟨ Print two lines using the tricky pseudoprinted information 347 ⟩ ≡
  if *trick_count* = 1000000 **then** *set_trick_count*;   { *set_trick_count* must be performed }
  if *tally* < *trick_count* **then** *m* ← *tally* − *first_count*
  else *m* ← *trick_count* − *first_count*;   { context on line 2 }
  if *l* + *first_count* ≤ *half_error_line* **then**
    begin *p* ← 0; *n* ← *l* + *first_count*;
    end
  else begin *print*("..."); *p* ← *l* + *first_count* − *half_error_line* + 3; *n* ← *half_error_line*;
    end;
  for *q* ← *p* **to** *first_count* − 1 **do** *print_char*(*trick_buf*[*q* **mod** *error_line*]);
  print_ln;
  for *q* ← 1 **to** *n* **do** *print_visible_char*("␣");   { print *n* spaces to begin line 2 }
  if *m* + *n* ≤ *error_line* **then** *p* ← *first_count* + *m*
  else *p* ← *first_count* + (*error_line* − *n* − 3);
  for *q* ← *first_count* **to** *p* − 1 **do** *print_char*(*trick_buf*[*q* **mod** *error_line*]);
  if *m* + *n* > *error_line* **then** *print*("...")
This code is used in section 342.

348. But the trick is distracting us from our current goal, which is to understand the input state. So let's concentrate on the data structures that are being pseudoprinted as we finish up the *show_context* procedure.

⟨ Pseudoprint the line 348 ⟩ ≡
  begin_pseudoprint;
  if *buffer*[*limit*] = *end_line_char* **then** *j* ← *limit*
  else *j* ← *limit* + 1;   { determine the effective end of the line }
  if *j* > 0 **then**
    for *i* ← *start* **to** *j* − 1 **do**
      begin if *i* = *loc* **then** *set_trick_count*;
      print_char(*buffer*[*i*]);
      end
This code is used in section 342.

349. ⟨ Pseudoprint the token list 349 ⟩ ≡
  begin_pseudoprint;
  if *token_type* < *macro* **then** *show_token_list*(*start*, *loc*, 100000)
  else *show_token_list*(*link*(*start*), *loc*, 100000)   { avoid reference count }
This code is used in section 342.

350. Here is the missing piece of *show_token_list* that is activated when the token beginning line 2 is about to be shown:

⟨ Do magic computation 350 ⟩ ≡
  set_trick_count
This code is used in section 322.

351.   Maintaining the input stacks.   The following subroutines change the input status in commonly needed ways.

First comes *push_input*, which stores the current state and creates a new level (having, initially, the same properties as the old).

> **define** *push_input* ≡   { enter a new input level, save the old }
>   **begin if** *input_ptr* > *max_in_stack* **then**
>   **begin** *max_in_stack* ← *input_ptr*;
>   **if** *input_ptr* = *stack_size* **then** *overflow*("input␣stack␣size", *stack_size*);
>   **end**;
>   *input_stack*[*input_ptr*] ← *cur_input*;   { stack the record }
>   *incr*(*input_ptr*);
>   **end**

352.   And of course what goes up must come down.

> **define** *pop_input* ≡   { leave an input level, re-enter the old }
>   **begin** *decr*(*input_ptr*); *cur_input* ← *input_stack*[*input_ptr*];
>   **end**

353.   Here is a procedure that starts a new level of token-list input, given a token list p and its type t. If $t = macro$, the calling routine should set *name* and *loc*.

> **define** *back_list*(#) ≡ *begin_token_list*(#, *backed_up*)   { backs up a simple token list }
> **define** *ins_list*(#) ≡ *begin_token_list*(#, *inserted*)   { inserts a simple token list }

procedure *begin_token_list*(*p* : *pointer*; *t* : *quarterword*);
  begin *push_input*; *state* ← *token_list*; *start* ← *p*; *token_type* ← *t*;
  if $t ≥ macro$ **then**   { the token list starts with a reference count }
    begin *add_token_ref*(*p*);
    if $t = macro$ **then** *param_start* ← *param_ptr*
    else begin *loc* ← *link*(*p*);
      if *tracing_macros* > 1 **then**
        begin *begin_diagnostic*; *print_nl*("");
        case *t* **of**
        mark_text: *print_esc*("mark");
        write_text: *print_esc*("write");
        othercases *print_cmd_chr*(*assign_toks*, *t* − *output_text* + *output_routine_loc*)
        endcases;
        print("->"); *token_show*(*p*); *end_diagnostic*(*false*);
        end;
      end;
    end
  else *loc* ← *p*;
  end;

354.   When a token list has been fully scanned, the following computations should be done as we leave that level of input. The *token_type* tends to be equal to either *backed_up* or *inserted* about 2/3 of the time.

procedure *end_token_list*;   { leave a token-list input level }
  begin if *token_type* ≥ *backed_up* **then**   { token list to be deleted }
    begin if *token_type* ≤ *inserted* **then** *flush_list*(*start*)
    else begin *delete_token_ref*(*start*);   { update reference count }
      if *token_type* = *macro* **then**   { parameters must be flushed }
        while *param_ptr* > *param_start* **do**
          begin *decr*(*param_ptr*); *flush_list*(*param_stack*[*param_ptr*]);
          end;
      end;
    end
  else if *token_type* = *u_template* **then**
    if *align_state* > 500000 **then** *align_state* ← 0
    else *fatal_error*("(interwoven␣alignment␣preambles␣are␣not␣allowed)");
  pop_input; *check_interrupt*;
  end;

355.   Sometimes TEX has read too far and wants to "unscan" what it has seen. The *back_input* procedure takes care of this by putting the token just scanned back into the input stream, ready to be read again. This procedure can be used only if *cur_tok* represents the token to be replaced. Some applications of TEX use this procedure a lot, so it has been slightly optimized for speed.

procedure *back_input*;   { undoes one token of input }
  var *p*: *pointer*;   { a token list of length one }
  begin while (*state* = *token_list*) ∧ (*loc* = *null*) ∧ (*token_type* ≠ *v_template*) **do** *end_token_list*;
      { conserve stack space }
  p ← *get_avail*; *info*(*p*) ← *cur_tok*;
  if *cur_tok* < *right_brace_limit* **then**
    if *cur_tok* < *left_brace_limit* **then** *decr*(*align_state*)
    else *incr*(*align_state*);
  push_input; *state* ← *token_list*; *start* ← *p*; *token_type* ← *backed_up*; *loc* ← *p*;
    { that was *back_list*(*p*), without procedure overhead }
  end;

356.   ⟨ Insert token *p* into TEX's input 356 ⟩ ≡
  begin *t* ← *cur_tok*; *cur_tok* ← *p*;
  if *a* **then**
    begin *p* ← *get_avail*; *info*(*p*) ← *cur_tok*; *link*(*p*) ← *loc*; *loc* ← *p*; *start* ← *p*;
    if *cur_tok* < *right_brace_limit* **then**
      if *cur_tok* < *left_brace_limit* **then** *decr*(*align_state*)
      else *incr*(*align_state*);
    end
  else begin *back_input*; *a* ← *eTeX_ex*;
    end;
  cur_tok ← *t*;
  end

This code is used in section 312.

357.   The *back_error* routine is used when we want to replace an offending token just before issuing an error message. This routine, like *back_input*, requires that *cur_tok* has been set. We disable interrupts during the call of *back_input* so that the help message won't be lost.

procedure *back_error*;   { back up one token and call *error* }
  begin *OK_to_interrupt* ← *false*; *back_input*; *OK_to_interrupt* ← *true*; *error*;
  end;

procedure *ins_error*;   { back up one inserted token and call *error* }
  begin *OK_to_interrupt* ← *false*; *back_input*; *token_type* ← *inserted*; *OK_to_interrupt* ← *true*; *error*;
  end;

358.   The *begin_file_reading* procedure starts a new level of input for lines of characters to be read from a file, or as an insertion from the terminal. It does not take care of opening the file, nor does it set *loc* or *limit* or *line*.

procedure *begin_file_reading*;
  begin if *in_open* = *max_in_open* **then** *overflow*("text␣input␣levels", *max_in_open*);
  if *first* = *buf_size* **then** *overflow*("buffer␣size", *buf_size*);
  incr(*in_open*); *push_input*; *index* ← *in_open*; *eof_seen*[*index*] ← *false*;
  grp_stack[*index*] ← *cur_boundary*; *if_stack*[*index*] ← *cond_ptr*; *line_stack*[*index*] ← *line*; *start* ← *first*;
  state ← *mid_line*; *name* ← 0;   { *terminal_input* is now *true* }
  end;

359.   Conversely, the variables must be downdated when such a level of input is finished:

procedure *end_file_reading*;
  begin *first* ← *start*; *line* ← *line_stack*[*index*];
  if (*name* = 18) ∨ (*name* = 19) **then** *pseudo_close*
  else if *name* > 17 **then** *u_close*(*cur_file*);   { forget it }
  pop_input; *decr*(*in_open*);
  end;

360.   In order to keep the stack from overflowing during a long sequence of inserted '\show' commands, the following routine removes completed error-inserted lines from memory.

procedure *clear_for_error_prompt*;
  begin while (*state* ≠ *token_list*) ∧ *terminal_input* ∧ (*input_ptr* > 0) ∧ (*loc* > *limit*) **do** *end_file_reading*;
  print_ln; *clear_terminal*;
  end;

361.   To get TEX's whole input mechanism going, we perform the following actions.

⟨ Initialize the input routines 361 ⟩ ≡
  begin *input_ptr* ← 0; *max_in_stack* ← 0; *in_open* ← 0; *open_parens* ← 0; *max_buf_stack* ← 0;
  grp_stack[0] ← 0; *if_stack*[0] ← *null*; *param_ptr* ← 0; *max_param_stack* ← 0; *first* ← *buf_size*;
  repeat *buffer*[*first*] ← 0; *decr*(*first*);
  until *first* = 0;
  scanner_status ← *normal*; *warning_index* ← *null*; *first* ← 1; *state* ← *new_line*; *start* ← 1; *index* ← 0;
  line ← 0; *name* ← 0; *force_eof* ← *false*; *align_state* ← 1000000;
  if ¬*init_terminal* **then goto** *final_end*;
  limit ← *last*; *first* ← *last* + 1;   { *init_terminal* has set *loc* and *last* }
  end

This code is used in section 1391.

362.   Getting the next token.   The heart of TEX's input mechanism is the *get_next* procedure, which we shall develop in the next few sections of the program. Perhaps we shouldn't actually call it the "heart," however, because it really acts as TEX's eyes and mouth, reading the source files and gobbling them up. And it also helps TEX to regurgitate stored token lists that are to be processed again.

The main duty of *get_next* is to input one token and to set *cur_cmd* and *cur_chr* to that token's command code and modifier. Furthermore, if the input token is a control sequence, the *eqtb* location of that control sequence is stored in *cur_cs*; otherwise *cur_cs* is set to zero.

Underlying this simple description is a certain amount of complexity because of all the cases that need to be handled. However, the inner loop of *get_next* is reasonably short and fast.

When *get_next* is asked to get the next token of a \read line, it sets *cur_cmd* = *cur_chr* = *cur_cs* = 0 in the case that no more tokens appear on that line. (There might not be any tokens at all, if the *end_line_char* has *ignore* as its catcode.)

363.   The value of *par_loc* is the *eqtb* address of '\par'. This quantity is needed because a blank line of input is supposed to be exactly equivalent to the appearance of \par; we must set *cur_cs* ← *par_loc* when detecting a blank line.

⟨ Global variables 13 ⟩ +≡
par_loc: *pointer*;   { location of '\par' in *eqtb* }
par_token: *halfword*;   { token representing '\par' }

364.   ⟨ Put each of TEX's primitives into the hash table 252 ⟩ +≡
  primitive("par", *par_end*, *too_big_usv*);   { cf. *scan_file_name* }
  par_loc ← *cur_val*; *par_token* ← *cs_token_flag* + *par_loc*;

365.   ⟨ Cases of *print_cmd_chr* for symbolic printing of primitives 253 ⟩ +≡
par_end: *print_esc*("par");

366.   Before getting into *get_next*, let's consider the subroutine that is called when an '\outer' control sequence has been scanned or when the end of a file has been reached. These two cases are distinguished by *cur_cs*, which is zero at the end of a file.

procedure *check_outer_validity*;
  var *p*: *pointer*;   { points to inserted token list }
    q: *pointer*;   { auxiliary pointer }
  begin if *scanner_status* ≠ *normal* **then**
    begin *deletions_allowed* ← *false*; ⟨ Back up an outer control sequence so that it can be reread 367 ⟩;
    if *scanner_status* > *skipping* **then** ⟨ Tell the user what has run away and try to recover 368 ⟩
    else begin *print_err*("Incomplete␣"); *print_cmd_chr*(*if_test*, *cur_if*);
      print(";␣all␣text␣was␣ignored␣after␣line␣"); *print_int*(*skip_line*);
      help3("A␣forbidden␣control␣sequence␣occurred␣in␣skipped␣text.")
      ("This␣kind␣of␣error␣happens␣when␣you␣say␣`\if...´␣and␣forget")
      ("the␣matching␣`\fi´.␣I´ve␣inserted␣a␣`\fi´;␣this␣might␣work.");
      if *cur_cs* ≠ 0 **then** *cur_cs* ← 0
      else *help_line*[2] ← "The␣file␣ended␣while␣I␣was␣skipping␣conditional␣text.";
      cur_tok ← *cs_token_flag* + *frozen_fi*; *ins_error*;
      end;
    deletions_allowed ← *true*;
    end;
  end;

367.   An outer control sequence that occurs in a \read will not be reread, since the error recovery for
\read is not very powerful.

⟨ Back up an outer control sequence so that it can be reread 367 ⟩ ≡
  if $cur\_cs \neq 0$ **then**
    begin if $(state = token\_list) \vee (name < 1) \vee (name > 17)$ **then**
      begin $p \leftarrow get\_avail$; $info(p) \leftarrow cs\_token\_flag + cur\_cs$; $back\_list(p)$;
          { prepare to read the control sequence again }
      end;
    $cur\_cmd \leftarrow spacer$; $cur\_chr \leftarrow$ "␣";   { replace it by a space }
    end

This code is used in section 366.

368.   ⟨ Tell the user what has run away and try to recover 368 ⟩ ≡
  begin $runaway$;   { print a definition, argument, or preamble }
  if $cur\_cs = 0$ **then** $print\_err($"File␣ended"$)$
  else begin $cur\_cs \leftarrow 0$; $print\_err($"Forbidden␣control␣sequence␣found"$)$;
    end;
  $print($"␣while␣scanning␣"$)$; ⟨ Print either 'definition' or 'use' or 'preamble' or 'text', and insert
      tokens that should lead to recovery 369 ⟩;
  $print($"␣of␣"$)$; $sprint\_cs(warning\_index)$;
  $help4($"I␣suspect␣you␣have␣forgotten␣a␣`}´,␣causing␣me"$)$
  $($"to␣read␣past␣where␣you␣wanted␣me␣to␣stop."$)$
  $($"I´ll␣try␣to␣recover;␣but␣if␣the␣error␣is␣serious,"$)$
  $($"you´d␣better␣type␣`E´␣or␣`X´␣now␣and␣fix␣your␣file."$)$;
  $error$;
  end

This code is used in section 366.

369.   The recovery procedure can't be fully understood without knowing more about the T$_E$X routines that
should be aborted, but we can sketch the ideas here: For a runaway definition or a runaway balanced text
we will insert a right brace; for a runaway preamble, we will insert a special \cr token and a right brace;
and for a runaway argument, we will set $long\_state$ to $outer\_call$ and insert \par.

⟨ Print either 'definition' or 'use' or 'preamble' or 'text', and insert tokens that should lead to
      recovery 369 ⟩ ≡
  $p \leftarrow get\_avail$;
  case $scanner\_status$ **of**
  $defining$: **begin** $print($"definition"$)$; $info(p) \leftarrow right\_brace\_token +$ "}";
    end;
  $matching$: **begin** $print($"use"$)$; $info(p) \leftarrow par\_token$; $long\_state \leftarrow outer\_call$;
    end;
  $aligning$: **begin** $print($"preamble"$)$; $info(p) \leftarrow right\_brace\_token +$ "}"; $q \leftarrow p$; $p \leftarrow get\_avail$;
    $link(p) \leftarrow q$; $info(p) \leftarrow cs\_token\_flag + frozen\_cr$; $align\_state \leftarrow -1000000$;
    end;
  $absorbing$: **begin** $print($"text"$)$; $info(p) \leftarrow right\_brace\_token +$ "}";
    end;
  end;   { there are no other cases }
  $ins\_list(p)$

This code is used in section 368.

370.   We need to mention a procedure here that may be called by get_next.

procedure $firm\_up\_the\_line$; $forward$;

371.   Now we're ready to take the plunge into *get_next* itself. Parts of this routine are executed more often than any other instructions of TEX.

> **define** *switch* = 25   { a label in *get_next* }
> **define** *start_cs* = 26   { another }
> **define** *not_exp* = 27

procedure *get_next*;   { sets *cur_cmd*, *cur_chr*, *cur_cs* to next token }
> **label** *restart*,   { go here to get the next input token }
>> *switch*,   { go here to eat the next character from a file }
>> *reswitch*,   { go here to digest it again }
>> *start_cs*,   { go here to start looking for a control sequence }
>> *found*,   { go here when a control sequence has been found }
>> *not_exp*,   { go here when 'turned out not to start an expanded code }
>> *exit*;   { go here when the next input token has been got }
> **var** *k*: 0 .. *buf_size*;   { an index into *buffer* }
>> *t*: *halfword*;   { a token }
>> *cat*: 0 .. *max_char_code*;   { *cat_code*(*cur_chr*), usually }
>> *c*: *UnicodeScalar*;   { constituent of a possible expanded code }
>> *lower*: *UTF16_code*;   { lower surrogate of a possible UTF-16 compound }
>> *d*: *small_number*;   { number of excess characters in an expanded code }
>> *sup_count*: *small_number*;   { number of identical *sup_mark* characters }
> **begin** *restart*: *cur_cs* ← 0;
> **if** *state* ≠ *token_list* **then** ⟨Input from external file, **goto** *restart* if no input found 373⟩
> **else** ⟨Input from token list, **goto** *restart* if end of list or if a parameter needs to be expanded 387⟩;
> ⟨If an alignment entry has just ended, take appropriate action 372⟩;
exit: **end**;

372.   An alignment entry ends when a tab or \cr occurs, provided that the current level of braces is the same as the level that was present at the beginning of that alignment entry; i.e., provided that *align_state* has returned to the value it had after the ⟨u_j⟩ template for that entry.

⟨If an alignment entry has just ended, take appropriate action 372⟩ ≡
> **if** *cur_cmd* ≤ *car_ret* **then**
>> **if** *cur_cmd* ≥ *tab_mark* **then**
>>> **if** *align_state* = 0 **then** ⟨Insert the ⟨v_j⟩ template and **goto** *restart* 837⟩

This code is used in section 371.

373. ⟨Input from external file, **goto** *restart* if no input found 373⟩ ≡
  begin *switch*: **if** *loc* ≤ *limit* **then**   {current line not yet finished}
    begin *cur_chr* ← *buffer*[*loc*]; *incr*(*loc*);
    if (*cur_chr* ≥ ″D800) ∧ (*cur_chr* < ″DC00) ∧ (*loc* ≤ *limit*) ∧ (*buffer*[*loc*] ≥ ″DC00) ∧ (*buffer*[*loc*] < ″E000)
        then
      begin *lower* ← *buffer*[*loc*] − ″DC00; *incr*(*loc*); *cur_chr* ← ″10000 + (*cur_chr* − ″D800) ∗ 1024 + *lower*;
      end;
  reswitch: *cur_cmd* ← *cat_code*(*cur_chr*); ⟨Change state if necessary, and **goto** *switch* if the current
        character should be ignored, or **goto** *reswitch* if the current character changes to another 374⟩;
    end
  else begin *state* ← *new_line*;
    ⟨Move to next line of file, or **goto** *restart* if there is no next line, or **return** if a \read line has
        finished 390⟩;
    check_interrupt; **goto** *switch*;
    end;
  end

This code is used in section 371.

374.   The following 48-way switch accomplishes the scanning quickly, assuming that a decent Pascal
compiler has translated the code. Note that the numeric values for *mid_line*, *skip_blanks*, and *new_line*
are spaced apart from each other by *max_char_code* + 1, so we can add a character's command code to the
state to get a single number that characterizes both.

  define *any_state_plus*(#) ≡ *mid_line* + #, *skip_blanks* + #, *new_line* + #

⟨Change state if necessary, and **goto** *switch* if the current character should be ignored, or **goto** *reswitch* if
        the current character changes to another 374⟩ ≡
  case *state* + *cur_cmd* **of**
  ⟨Cases where character is ignored 375⟩: **goto** *switch*;
  any_state_plus(*escape*): ⟨Scan a control sequence and set *state* ← *skip_blanks* or *mid_line* 384⟩;
  any_state_plus(*active_char*): ⟨Process an active-character control sequence and set *state* ← *mid_line* 383⟩;
  any_state_plus(*sup_mark*): ⟨If this *sup_mark* starts an expanded character like ^^A or ^^df, then **goto**
        reswitch, otherwise set *state* ← *mid_line* 382⟩;
  any_state_plus(*invalid_char*): ⟨Decry the invalid character and **goto** *restart* 376⟩;
  ⟨Handle situations involving spaces, braces, changes of state 377⟩
  othercases *do_nothing*
  endcases

This code is used in section 373.

375.   ⟨Cases where character is ignored 375⟩ ≡
  any_state_plus(*ignore*), *skip_blanks* + *spacer*, *new_line* + *spacer*

This code is used in section 374.

376.   We go to *restart* instead of to *switch*, because *state* might equal *token_list* after the error has been
dealt with (cf. *clear_for_error_prompt*).

⟨Decry the invalid character and **goto** *restart* 376⟩ ≡
  begin *print_err*("Text␣line␣contains␣an␣invalid␣character");
  help2("A␣funny␣symbol␣that␣I␣can´t␣read␣has␣just␣been␣input.")
  ("Continue,␣and␣I´ll␣forget␣that␣it␣ever␣happened.");
  deletions_allowed ← *false*; *error*; *deletions_allowed* ← *true*; **goto** *restart*;
  end

This code is used in section 374.

377.   **define** $add\_delims\_to(\#) \equiv \# + math\_shift, \# + tab\_mark, \# + mac\_param, \# + sub\_mark, \# + letter,$
$\# + other\_char$

⟨Handle situations involving spaces, braces, changes of state 377⟩ ≡
$mid\_line + spacer$: ⟨Enter $skip\_blanks$ state, emit a space 379⟩;
$mid\_line + car\_ret$: ⟨Finish line, emit a space 378⟩;

$new\_line + car\_ret$: ⟨Finish line, emit a \par 381⟩;
$mid\_line + left\_brace$: $incr(align\_state)$;
$skip\_blanks + left\_brace, new\_line + left\_brace$: **begin** $state \leftarrow mid\_line$; $incr(align\_state)$;
  end;
$mid\_line + right\_brace$: $decr(align\_state)$;
$skip\_blanks + right\_brace, new\_line + right\_brace$: **begin** $state \leftarrow mid\_line$; $decr(align\_state)$;
  end;
$add\_delims\_to(skip\_blanks), add\_delims\_to(new\_line)$: $state \leftarrow mid\_line$;
This code is used in section 374.

378.   When a character of type *spacer* gets through, its character code is changed to "␣" = ´40´. This
means that the ASCII codes for tab and space, and for the space inserted at the end of a line, will be treated
alike when macro parameters are being matched. We do this since such characters are indistinguishable on
most computer terminal displays.

⟨Finish line, emit a space 378⟩ ≡
  begin $loc \leftarrow limit + 1$; $cur\_cmd \leftarrow spacer$; $cur\_chr \leftarrow$ "␣";
  end

This code is used in section 377.

379.   The following code is performed only when $cur\_cmd = spacer$.

⟨Enter $skip\_blanks$ state, emit a space 379⟩ ≡
  begin $state \leftarrow skip\_blanks$; $cur\_chr \leftarrow$ "␣";
  end

This code is used in section 377.

380.   ⟨Finish line, **goto** $switch$ 380⟩ ≡
  begin $loc \leftarrow limit + 1$; **goto** $switch$;
  end

This code is used in section 377.

381.   ⟨Finish line, emit a \par 381⟩ ≡
  begin $loc \leftarrow limit + 1$; $cur\_cs \leftarrow par\_loc$; $cur\_cmd \leftarrow eq\_type(cur\_cs)$; $cur\_chr \leftarrow equiv(cur\_cs)$;
  if $cur\_cmd \geq outer\_call$ **then** $check\_outer\_validity$;
  end

This code is used in section 377.

382.   Notice that a code like `^^8` becomes `x` if not followed by a hex digit.

  define $is\_hex(\#) \equiv (((\# \geq "0") \wedge (\# \leq "9")) \vee ((\# \geq "a") \wedge (\# \leq "f")))$
  define $hex\_to\_cur\_chr \equiv$
              if $c \leq "9"$ **then** $cur\_chr \leftarrow c - "0"$ **else** $cur\_chr \leftarrow c - "a" + 10;$
          if $cc \leq "9"$ **then** $cur\_chr \leftarrow 16 * cur\_chr + cc - "0"$
          else $cur\_chr \leftarrow 16 * cur\_chr + cc - "a" + 10$
  define $long\_hex\_to\_cur\_chr \equiv$
              if $c \leq "9"$ **then** $cur\_chr \leftarrow c - "0"$ **else** $cur\_chr \leftarrow c - "a" + 10;$
          if $cc \leq "9"$ **then** $cur\_chr \leftarrow 16 * cur\_chr + cc - "0"$
          else $cur\_chr \leftarrow 16 * cur\_chr + cc - "a" + 10;$

        $loc \leftarrow loc + 2 * sup\_count - 1;$ **goto** $reswitch;$
        end;
not_exp: $state \leftarrow mid\_line;$
  end

This code is used in section 374.

383. ⟨ Process an active-character control sequence and set *state* ← *mid_line* 383 ⟩ ≡
  begin *cur_cs* ← *cur_chr* + *active_base*; *cur_cmd* ← *eq_type*(*cur_cs*); *cur_chr* ← *equiv*(*cur_cs*);
  state ← *mid_line*;
  if *cur_cmd* ≥ *outer_call* **then** *check_outer_validity*;
  end

This code is used in section 374.

384. Control sequence names are scanned only when they appear in some line of a file; once they have
been scanned the first time, their *eqtb* location serves as a unique identification, so T$_{\text{E}}$X doesn't need to refer
to the original name any more except when it prints the equivalent in symbolic form.

  The program that scans a control sequence has been written carefully in order to avoid the blowups that
might otherwise occur if a malicious user tried something like '\catcode´15=0'. The algorithm might look
at *buffer*[*limit* + 1], but it never looks at *buffer*[*limit* + 2].

  If expanded characters like '^^A' or '^^df' appear in or just following a control sequence name, they are
converted to single characters in the buffer and the process is repeated, slowly but surely.

⟨ Scan a control sequence and set *state* ← *skip_blanks* or *mid_line* 384 ⟩ ≡
  begin if *loc* > *limit* **then** *cur_cs* ← *null_cs*   { *state* is irrelevant in this case }
  else begin *start_cs*: *k* ← *loc*; *cur_chr* ← *buffer*[*k*]; *cat* ← *cat_code*(*cur_chr*); *incr*(*k*);

      begin *end_file_reading*; **goto** *restart*;   {resume previous level }
      end;
    if *selector* < *log_only* **then** *open_log_file*;
    if *interaction* > *nonstop_mode* **then**
      begin if *end_line_char_inactive* **then** *incr*(*limit*);
      if *limit* = *start* **then**   {previous line was empty }
        print_nl("(Please␣type␣a␣command␣or␣say␣`\end´)");
      print_ln; *first* ← *start*; *prompt_input*("*");   {input on-line into *buffer* }
      limit ← *last*;
      if *end_line_char_inactive* **then** *decr*(*limit*)
      else *buffer*[*limit*] ← *end_line_char*;
      first ← *limit* + 1; *loc* ← *start*;
      end
    else *fatal_error*("***␣(job␣aborted,␣no␣legal␣\end␣found)");
          {nonstop mode, which is intended for overnight batch processing, never waits for on-line input }
    end

This code is used in section 373.

391. The global variable *force_eof* is normally *false*; it is set *true* by an \endinput command.
⟨Global variables 13⟩ +≡
force_eof: *boolean*;   {should the next \input be aborted early? }

392. ⟨Read next line of file into *buffer*, or **goto** *restart* if the file has ended 392⟩ ≡
  begin *incr*(*line*); *first* ← *start*;
  if ¬*force_eof* **then**
    if *name* ≤ 19 **then**
      begin if *pseudo_input* **then**   {not end of file}
        firm_up_the_line   {this sets *limit*}
      else if (*every_eof* ≠ *null*) ∧ ¬*eof_seen*[*index*] **then**
          begin *limit* ← *first* − 1; *eof_seen*[*index*] ← *true*;   {fake one empty line}
          begin_token_list(*every_eof*, *every_eof_text*); **goto** *restart*;
          end
        else *force_eof* ← *true*;
      end
    else begin if *input_ln*(*cur_file*, *true*) **then**   {not end of file}
        firm_up_the_line   {this sets *limit*}
      else if (*every_eof* ≠ *null*) ∧ ¬*eof_seen*[*index*] **then**
          begin *limit* ← *first* − 1; *eof_seen*[*index*] ← *true*;   {fake one empty line}
          begin_token_list(*every_eof*, *every_eof_text*); **goto** *restart*;
          end
        else *force_eof* ← *true*;
      end;
  if *force_eof* **then**
    begin if *tracing_nesting* > 0 **then**
      if (*grp_stack*[*in_open*] ≠ *cur_boundary*) ∨ (*if_stack*[*in_open*] ≠ *cond_ptr*) **then** *file_warning*;
            {give warning for some unfinished groups and/or conditionals}
    if *name* ≥ 19 **then**
      begin *print_char*(")"); *decr*(*open_parens*); *update_terminal*;   {show user that file has been read}
      end;
    force_eof ← *false*; *end_file_reading*;   {resume previous level}
    check_outer_validity; **goto** *restart*;
    end;
  if *end_line_char_inactive* **then** *decr*(*limit*)
  else *buffer*[*limit*] ← *end_line_char*;
  first ← *limit* + 1; *loc* ← *start*;   {ready to read}
  end

This code is used in section 390.

393.   If the user has set the *pausing* parameter to some positive value, and if nonstop mode has not been selected, each line of input is displayed on the terminal and the transcript file, followed by '=>'. TEX waits for a response. If the response is simply *carriage_return*, the line is accepted as it stands, otherwise the line typed is used instead of the line in the file.

procedure *firm_up_the_line*;
  var *k*: 0 . . *buf_size*;   { an index into *buffer* }
  begin *limit* ← *last*;
  if *pausing* > 0 **then**
    if *interaction* > *nonstop_mode* **then**
      begin *wake_up_terminal*; *print_ln*;
      if *start* < *limit* **then**
        for *k* ← *start* **to** *limit* − 1 **do** *print*(*buffer*[*k*]);
      first ← *limit*; *prompt_input*("=>");   { wait for user response }
      if *last* > *first* **then**
        begin for *k* ← *first* **to** *last* − 1 **do**   { move line down in buffer }
          buffer[*k* + *start* − *first*] ← *buffer*[*k*];
        limit ← *start* + *last* − *first*;
        end;
      end;
  end;

394.   Since *get_next* is used so frequently in TEX, it is convenient to define three related procedures that do a little more:

get_token not only sets *cur_cmd* and *cur_chr*, it also sets *cur_tok*, a packed halfword version of the current token.

get_x_token, meaning "get an expanded token," is like *get_token*, but if the current token turns out to be a user-defined control sequence (i.e., a macro call), or a conditional, or something like \topmark or \expandafter or \csname, it is eliminated from the input by beginning the expansion of the macro or the evaluation of the conditional.

x_token is like *get_x_token* except that it assumes that *get_next* has already been called.

In fact, these three procedures account for almost every use of *get_next*.

395.   No new control sequences will be defined except during a call of *get_token*, or when \csname compresses a token list, because *no_new_control_sequence* is always *true* at other times.

procedure *get_token*;   { sets *cur_cmd*, *cur_chr*, *cur_tok* }
  begin *no_new_control_sequence* ← *false*; *get_next*; *no_new_control_sequence* ← *true*;
  if *cur_cs* = 0 **then** *cur_tok* ← (*cur_cmd* ∗ *max_char_val*) + *cur_chr*
  else *cur_tok* ← *cs_token_flag* + *cur_cs*;
  end;

396.   Expanding the next token.   Only a dozen or so command codes > *max_command* can possibly be returned by *get_next*; in increasing order, they are *undefined_cs*, *expand_after*, *no_expand*, *input*, *if_test*, *fi_or_else*, *cs_name*, *convert*, *the*, *top_bot_mark*, *call*, *long_call*, *outer_call*, *long_outer_call*, and *end_template*.

The *expand* subroutine is used when *cur_cmd* > *max_command*. It removes a "call" or a conditional or one of the other special operations just listed. It follows that *expand* might invoke itself recursively. In all cases, *expand* destroys the current token, but it sets things up so that the next *get_next* will deliver the appropriate next token. The value of *cur_tok* need not be known when *expand* is called.

Since several of the basic scanning routines communicate via global variables, their values are saved as local variables of *expand* so that recursive calls don't invalidate them.

⟨Declare the procedure called *macro_call* 423⟩

  fi_or_else: ⟨Terminate the current conditional and skip to \fi 545⟩;
  input: ⟨Initiate or terminate input from a file 412⟩;
  othercases ⟨Complain about an undefined macro 404⟩
  endcases;
  end
This code is used in section 396.

400. It takes only a little shuffling to do what TEX calls \expandafter.

⟨Expand the token after the next token 400⟩ ≡
  begin *get_token*; *t* ← *cur_tok*; *get_token*;
  if *cur_cmd* > *max_command* **then** *expand* **else** *back_input*;
  cur_tok ← *t*; *back_input*;
  end
This code is used in section 399.

401. The implementation of \noexpand is a bit trickier, because it is necessary to insert a special '*dont_expand*' marker into TEX's reading mechanism. This special marker is processed by *get_next*, but it does not slow down the inner loop.

Since \outer macros might arise here, we must also clear the *scanner_status* temporarily.

⟨Suppress expansion of the next token 401⟩ ≡
  begin *save_scanner_status* ← *scanner_status*; *scanner_status* ← *normal*; *get_token*;
  scanner_status ← *save_scanner_status*; *t* ← *cur_tok*; *back_input*;
      {now *start* and *loc* point to the backed-up token *t*}
  if *t* ≥ *cs_token_flag* **then**
      begin *p* ← *get_avail*; *info*(*p*) ← *cs_token_flag* + *frozen_dont_expand*; *link*(*p*) ← *loc*; *start* ← *p*;
      loc ← *p*;
      end;
  end
This code is used in section 399.

402. The \primitive handling. If the primitive meaning of the next token is an expandable command, it suffices to replace the current token with the primitive one and restart *expand*/

Otherwise, the token we just read has to be pushed back, as well as a token matching the internal form of \primitive, that is sneaked in as an alternate form of *ignore_spaces*.

Simply pushing back a token that matches the correct internal command does not work, because approach would not survive roundtripping to a temporary file.

⟨ Implement \primitive 402 ⟩ ≡

  begin *save_scanner_status* ← *scanner_status*; *scanner_status* ← *normal*; *get_token*;
  scanner_status ← *save_scanner_status*;
  if *cur_cs* < *hash_base* **then** *cur_cs* ← *prim_lookup*(*cur_cs* − *single_base*)
  else *cur_cs* ← *prim_lookup*(*text*(*cur_cs*));
  if *cur_cs* ≠ *undefined_primitive* **then**
    begin *t* ← *prim_eq_type*(*cur_cs*);
    if *t* > *max_command* **then**
      begin *cur_cmd* ← *t*; *cur_chr* ← *prim_equiv*(*cur_cs*);
      cur_tok ← (*cur_cmd* ∗ *max_char_val*) + *cur_chr*; *cur_cs* ← 0; **goto** *reswitch*;
      end
    else begin *back_input*; { now *loc* and *start* point to a one-item list }
      p ← *get_avail*; *info*(*p*) ← *cs_token_flag* + *frozen_primitive*; *link*(*p*) ← *loc*; *loc* ← *p*; *start* ← *p*;
      end
    end;
  end

This code is used in section 399.

403. This block deals with unexpandable \primitive appearing at a spot where an integer or an internal values should have been found. It fetches the next token then resets *cur_cmd*, *cur_cs*, and *cur_tok*, based on the primitive value of that token. No expansion takes place, because the next token may be all sorts of things. This could trigger further expansion creating new errors.

⟨ Reset *cur_tok* for unexpandable primitives, goto restart 403 ⟩ ≡

  begin *get_token*;
  if *cur_cs* < *hash_base* **then** *cur_cs* ← *prim_lookup*(*cur_cs* − *single_base*)
  else *cur_cs* ← *prim_lookup*(*text*(*cur_cs*));
  if *cur_cs* ≠ *undefined_primitive* **then**
    begin *cur_cmd* ← *prim_eq_type*(*cur_cs*); *cur_chr* ← *prim_equiv*(*cur_cs*);
    cur_cs ← *prim_eqtb_base* + *cur_cs*; *cur_tok* ← *cs_token_flag* + *cur_cs*;
    end
  else begin *cur_cmd* ← *relax*; *cur_chr* ← 0; *cur_tok* ← *cs_token_flag* + *frozen_relax*;
    cur_cs ← *frozen_relax*;
    end;
  goto *restart*;
  end

This code is used in sections 447 and 474.

404. ⟨Complain about an undefined macro 404⟩ ≡
  begin *print_err*("Undefined␣control␣sequence");
  help5("The␣control␣sequence␣at␣the␣end␣of␣the␣top␣line")
  ("of␣your␣error␣message␣was␣never␣\def´ed.␣If␣you␣have")
  ("misspelled␣it␣(e.g.,␣`\hobx´),␣type␣`I´␣and␣the␣correct")
  ("spelling␣(e.g.,␣`I\hbox´).␣Otherwise␣just␣continue,")
  ("and␣I´ll␣forget␣about␣whatever␣was␣undefined."); *error*;
  end

This code is used in section 399.

405. The *expand* procedure and some other routines that construct token lists find it convenient to use
the following macros, which are valid only if the variables *p* and *q* are reserved for token-list building.

  define *store_new_token*(#) ≡
          begin *q* ← *get_avail*; *link*(*p*) ← *q*; *info*(*q*) ← #; *p* ← *q*; { *link*(*p*) is *null* }
          end
  define *fast_store_new_token*(#) ≡
          begin *fast_get_avail*(*q*); *link*(*p*) ← *q*; *info*(*q*) ← #; *p* ← *q*; { *link*(*p*) is *null* }
          end

406. ⟨Manufacture a control sequence name 406⟩ ≡
  begin *r* ← *get_avail*; *p* ← *r*; { head of the list of characters }
  b ← *is_in_csname*; *is_in_csname* ← *true*;
  repeat *get_x_token*;
    if *cur_cs* = 0 **then** *store_new_token*(*cur_tok*);
  until *cur_cs* ≠ 0;
  if *cur_cmd* ≠ *end_cs_name* **then** ⟨Complain about missing \endcsname 407⟩;
  is_in_csname ← *b*; ⟨Look up the characters of list *r* in the hash table, and set *cur_cs* 408⟩;
  flush_list(*r*);
  if *eq_type*(*cur_cs*) = *undefined_cs* **then**
    begin *eq_define*(*cur_cs*, *relax*, *too_big_usv*); { N.B.: The *save_stack* might change }
    end; { the control sequence will now match '\relax' }
  cur_tok ← *cur_cs* + *cs_token_flag*; *back_input*;
  end

This code is used in section 399.

407. ⟨Complain about missing \endcsname 407⟩ ≡
  begin *print_err*("Missing␣"); *print_esc*("endcsname"); *print*("␣inserted");
  help2("The␣control␣sequence␣marked␣<to␣be␣read␣again>␣should")
  ("not␣appear␣between␣\csname␣and␣\endcsname."); *back_error*;
  end

This code is used in sections 406 and 1578.

408. ⟨Look up the characters of list r in the hash table, and set cur_cs 408⟩ ≡
  $j \leftarrow first$; $p \leftarrow link(r)$;
  while $p \neq null$ **do**
    begin if $j \geq max\_buf\_stack$ **then**
      begin $max\_buf\_stack \leftarrow j + 1$;
      if $max\_buf\_stack = buf\_size$ **then** $overflow(\texttt{"buffer\_size"}, buf\_size)$;
      end;
    $buffer[j] \leftarrow info(p) \textbf{ mod } max\_char\_val$; $incr(j)$; $p \leftarrow link(p)$;
    end;
  if $(j > first + 1) \vee (buffer[first] > \texttt{"FFFF})$ **then**
    begin $no\_new\_control\_sequence \leftarrow false$; $cur\_cs \leftarrow id\_lookup(first, j - first)$;
    $no\_new\_control\_sequence \leftarrow true$;
    end
  else if $j = first$ **then** $cur\_cs \leftarrow null\_cs$ {the list is empty}
    else $cur\_cs \leftarrow single\_base + buffer[first]$ {the list has length one}
This code is used in section 406.

409. An $end\_template$ command is effectively changed to an $endv$ command by the following code. (The reason for this is discussed below; the $frozen\_end\_template$ at the end of the template has passed the $check\_outer\_validity$ test, so its mission of error detection has been accomplished.)

⟨Insert a token containing $frozen\_endv$ 409⟩ ≡
  begin $cur\_tok \leftarrow cs\_token\_flag + frozen\_endv$; $back\_input$;
  end

This code is used in section 396.

410. The processing of \input involves the $start\_input$ subroutine, which will be declared later; the processing of \endinput is trivial.

⟨Put each of TEX's primitives into the hash table 252⟩ +≡
  $primitive(\texttt{"input"}, input, 0)$;
  $primitive(\texttt{"endinput"}, input, 1)$;

411. ⟨Cases of $print\_cmd\_chr$ for symbolic printing of primitives 253⟩ +≡
$input$: **if** $chr\_code = 0$ **then** $print\_esc(\texttt{"input"})$
  ⟨Cases of $input$ for $print\_cmd\_chr$ 1559⟩
else $print\_esc(\texttt{"endinput"})$;

412. ⟨Initiate or terminate input from a file 412⟩ ≡
  if $cur\_chr = 1$ **then** $force\_eof \leftarrow true$
  ⟨Cases for $input$ 1560⟩
else if $name\_in\_progress$ **then** $insert\_relax$
  else $start\_input$
This code is used in section 399.

413. Sometimes the expansion looks too far ahead, so we want to insert a harmless \relax into the user's input.

⟨Declare the procedure called $insert\_relax$ 413⟩ ≡
procedure $insert\_relax$;
  begin $cur\_tok \leftarrow cs\_token\_flag + cur\_cs$; $back\_input$; $cur\_tok \leftarrow cs\_token\_flag + frozen\_relax$; $back\_input$;
  $token\_type \leftarrow inserted$;
  end;

This code is used in section 396.

414.   Here is a recursive procedure that is TEX's usual way to get the next token of input. It has been slightly optimized to take account of common cases.

procedure *get_x_token*;   { sets *cur_cmd*, *cur_chr*, *cur_tok*, and expands macros }
  label *restart*, *done*;
  begin *restart*: *get_next*;
  if *cur_cmd* ≤ *max_command* **then goto** *done*;
  if *cur_cmd* ≥ *call* **then**
    if *cur_cmd* < *end_template* **then** *macro_call*
    else begin *cur_cs* ← *frozen_endv*; *cur_cmd* ← *endv*; **goto** *done*;   { *cur_chr* = *null_list* }
      end
  else *expand*;
  goto *restart*;
done: **if** *cur_cs* = 0 **then** *cur_tok* ← (*cur_cmd* ∗ *max_char_val*) + *cur_chr*
  else *cur_tok* ← *cs_token_flag* + *cur_cs*;
  end;

415.   The *get_x_token* procedure is essentially equivalent to two consecutive procedure calls: *get_next*; *x_token*.

procedure *x_token*;   { *get_x_token* without the initial *get_next* }
  begin while *cur_cmd* > *max_command* **do**
    begin *expand*; *get_next*;
    end;
  if *cur_cs* = 0 **then** *cur_tok* ← (*cur_cmd* ∗ *max_char_val*) + *cur_chr*
  else *cur_tok* ← *cs_token_flag* + *cur_cs*;
  end;

416.   A control sequence that has been \def'ed by the user is expanded by TEX's *macro_call* procedure.
  Before we get into the details of *macro_call*, however, let's consider the treatment of primitives like \topmark, since they are essentially macros without parameters. The token lists for such marks are kept in a global array of five pointers; we refer to the individual entries of this array by symbolic names *top_mark*, etc. The value of *top_mark* is either *null* or a pointer to the reference count of a token list.

  define *marks_code* ≡ 5   { add this for \topmarks etc. }

  define *top_mark_code* = 0   { the mark in effect at the previous page break }
  define *first_mark_code* = 1   { the first mark between *top_mark* and *bot_mark* }
  define *bot_mark_code* = 2   { the mark in effect at the current page break }
  define *split_first_mark_code* = 3   { the first mark found by \vsplit }
  define *split_bot_mark_code* = 4   { the last mark found by \vsplit }
  define *top_mark* ≡ *cur_mark*[*top_mark_code*]
  define *first_mark* ≡ *cur_mark*[*first_mark_code*]
  define *bot_mark* ≡ *cur_mark*[*bot_mark_code*]
  define *split_first_mark* ≡ *cur_mark*[*split_first_mark_code*]
  define *split_bot_mark* ≡ *cur_mark*[*split_bot_mark_code*]

⟨ Global variables 13 ⟩ +≡
cur_mark: **array** [*top_mark_code* .. *split_bot_mark_code*] **of** *pointer*;   { token lists for marks }

417.   ⟨ Set initial values of key variables 23 ⟩ +≡
  top_mark ← *null*; *first_mark* ← *null*; *bot_mark* ← *null*; *split_first_mark* ← *null*; *split_bot_mark* ← *null*;

418. ⟨Put each of TEX's primitives into the hash table 252⟩ +≡
  primitive("topmark", *top_bot_mark*, *top_mark_code*);
  primitive("firstmark", *top_bot_mark*, *first_mark_code*);
  primitive("botmark", *top_bot_mark*, *bot_mark_code*);
  primitive("splitfirstmark", *top_bot_mark*, *split_first_mark_code*);
  primitive("splitbotmark", *top_bot_mark*, *split_bot_mark_code*);

419. ⟨Cases of *print_cmd_chr* for symbolic printing of primitives 253⟩ +≡
top_bot_mark: **begin case** (*chr_code* **mod** *marks_code*) **of**
  first_mark_code: *print_esc*("firstmark");
  bot_mark_code: *print_esc*("botmark");
  split_first_mark_code: *print_esc*("splitfirstmark");
  split_bot_mark_code: *print_esc*("splitbotmark");
  othercases *print_esc*("topmark")
  endcases;
  if *chr_code* ≥ *marks_code* **then** *print_char*("s");
  end;

420. The following code is activated when *cur_cmd* = *top_bot_mark* and when *cur_chr* is a code like *top_mark_code*.

⟨Insert the appropriate mark text into the scanner 420⟩ ≡
  begin *t* ← *cur_chr* **mod** *marks_code*;
  if *cur_chr* ≥ *marks_code* **then** *scan_register_num* **else** *cur_val* ← 0;
  if *cur_val* = 0 **then** *cur_ptr* ← *cur_mark*[*t*]
  else ⟨Compute the mark pointer for mark type *t* and class *cur_val* 1635⟩;
  if *cur_ptr* ≠ *null* **then** *begin_token_list*(*cur_ptr*, *mark_text*);
  end

This code is used in section 399.

421. Now let's consider *macro_call* itself, which is invoked when TEX is scanning a control sequence whose *cur_cmd* is either *call*, *long_call*, *outer_call*, or *long_outer_call*. The control sequence definition appears in the token list whose reference count is in location *cur_chr* of *mem*.

The global variable *long_state* will be set to *call* or to *long_call*, depending on whether or not the control sequence disallows \par in its parameters. The *get_next* routine will set *long_state* to *outer_call* and emit \par, if a file ends or if an \outer control sequence occurs in the midst of an argument.

⟨Global variables 13⟩ +≡
long_state: *call* .. *long_outer_call*;   {governs the acceptance of \par}

422. The parameters, if any, must be scanned before the macro is expanded. Parameters are token lists without reference counts. They are placed on an auxiliary stack called *pstack* while they are being scanned, since the *param_stack* may be losing entries during the matching process. (Note that *param_stack* can't be gaining entries, since *macro_call* is the only routine that puts anything onto *param_stack*, and it is not recursive.)

⟨Global variables 13⟩ +≡
pstack: **array** [0 .. 8] **of** *pointer*;   {arguments supplied to a macro}

423.   After parameter scanning is complete, the parameters are moved to the *param_stack*. Then the macro body is fed to the scanner; in other words, *macro_call* places the defined text of the control sequence at the top of TEX's input stack, so that *get_next* will proceed to read it next.

 The global variable *cur_cs* contains the *eqtb* address of the control sequence being expanded, when *macro_call* begins. If this control sequence has not been declared \long, i.e., if its command code in the *eq_type* field is not *long_call* or *long_outer_call*, its parameters are not allowed to contain the control sequence \par. If an illegal \par appears, the macro call is aborted, and the \par will be rescanned.

⟨ Declare the procedure called *macro_call* 423 ⟩ ≡

procedure *macro_call*;   { invokes a user-defined control sequence }
   label *exit*, *continue*, *done*, *done1*, *found*;
   var *r*: *pointer*;   { current node in the macro's token list }
      p: *pointer*;   { current node in parameter token list being built }
      q: *pointer*;   { new node being put into the token list }
      s: *pointer*;   { backup pointer for parameter matching }
      t: *pointer*;   { cycle pointer for backup recovery }
      u, *v*: *pointer*;   { auxiliary pointers for backup recovery }
      rbrace_ptr: *pointer*;   { one step before the last *right_brace* token }
      n: *small_number*;   { the number of parameters scanned }
      unbalance: *halfword*;   { unmatched left braces in current parameter }
      m: *halfword*;   { the number of tokens or groups (usually) }
      ref_count: *pointer*;   { start of the token list }
      save_scanner_status: *small_number*;   { *scanner_status* upon entry }
      save_warning_index: *pointer*;   { *warning_index* upon entry }
      match_chr: *ASCII_code*;   { character used in parameter }
   begin *save_scanner_status* ← *scanner_status*; *save_warning_index* ← *warning_index*;
   warning_index ← *cur_cs*; *ref_count* ← *cur_chr*; *r* ← *link*(*ref_count*); *n* ← 0;
   if *tracing_macros* > 0 **then** ⟨ Show the text of the macro being expanded 435 ⟩;
   if *info*(*r*) = *protected_token* **then** *r* ← *link*(*r*);
   if *info*(*r*) ≠ *end_match_token* **then** ⟨ Scan the parameters and make *link*(*r*) point to the macro body;
         but **return** if an illegal \par is detected 425 ⟩;
   ⟨ Feed the macro body and its parameters to the scanner 424 ⟩;
exit: *scanner_status* ← *save_scanner_status*; *warning_index* ← *save_warning_index*;
   end;

This code is used in section 396.

424.   Before we put a new token list on the input stack, it is wise to clean off all token lists that have recently been depleted. Then a user macro that ends with a call to itself will not require unbounded stack space.

⟨ Feed the macro body and its parameters to the scanner 424 ⟩ ≡
   while (*state* = *token_list*) ∧ (*loc* = *null*) ∧ (*token_type* ≠ *v_template*) **do** *end_token_list*;
         { conserve stack space }
   begin_token_list(*ref_count*, *macro*); *name* ← *warning_index*; *loc* ← *link*(*r*);
   if *n* > 0 **then**
      begin if *param_ptr* + *n* > *max_param_stack* **then**
         begin *max_param_stack* ← *param_ptr* + *n*;
         if *max_param_stack* > *param_size* **then** *overflow*("parameter␣stack␣size", *param_size*);
         end;
      for *m* ← 0 **to** *n* − 1 **do** *param_stack*[*param_ptr* + *m*] ← *pstack*[*m*];
      param_ptr ← *param_ptr* + *n*;
      end

This code is used in section 423.

425.   At this point, the reader will find it advisable to review the explanation of token list format that was presented earlier, since many aspects of that format are of importance chiefly in the *macro_call* routine.

The token list might begin with a string of compulsory tokens before the first *match* or *end_match*. In that case the macro name is supposed to be followed by those tokens; the following program will set $s = null$ to represent this restriction. Otherwise s will be set to the first token of a string that will delimit the next parameter.

⟨Scan the parameters and make *link*(*r*) point to the macro body; but **return** if an illegal \par is detected 425⟩ ≡

  begin *scanner_status* ← *matching*; *unbalance* ← 0; *long_state* ← *eq_type*(*cur_cs*);

  if *long_state* ≥ *outer_call* **then** *long_state* ← *long_state* − 2;

  repeat *link*(*temp_head*) ← *null*;

    if (*info*(*r*) ≥ *end_match_token*) ∨ (*info*(*r*) < *match_token*) **then** $s ← null$

    else begin *match_chr* ← *info*(*r*) − *match_token*; *s* ← *link*(*r*); *r* ← *s*; *p* ← *temp_head*; *m* ← 0;

      end;

    ⟨Scan a parameter until its delimiter string has been found; or, if $s = null$, simply scan the delimiter string 426⟩;

      { now *info*(*r*) is a token whose command code is either *match* or *end_match* }

  until *info*(*r*) = *end_match_token*;

  end

This code is used in section 423.

426.   If *info*(*r*) is a *match* or *end_match* command, it cannot be equal to any token found by *get_token*. Therefore an undelimited parameter—i.e., a *match* that is immediately followed by *match* or *end_match*— will always fail the test '*cur_tok* = *info*(*r*)' in the following algorithm.

⟨Scan a parameter until its delimiter string has been found; or, if $s = null$, simply scan the delimiter string 426⟩ ≡

continue: *get_token*;   { set *cur_tok* to the next token of input }

  if *cur_tok* = *info*(*r*) **then** ⟨Advance *r*; **goto** *found* if the parameter delimiter has been fully matched, otherwise **goto** *continue* 428⟩;

  ⟨Contribute the recently matched tokens to the current parameter, and **goto** *continue* if a partial match is still in effect; but abort if $s = null$ 431⟩;

  if *cur_tok* = *par_token* **then**

    if *long_state* ≠ *long_call* **then** ⟨Report a runaway argument and abort 430⟩;

  if *cur_tok* < *right_brace_limit* **then**

    if *cur_tok* < *left_brace_limit* **then** ⟨Contribute an entire group to the current parameter 433⟩

    else ⟨Report an extra right brace and **goto** *continue* 429⟩

  else ⟨Store the current token, but **goto** *continue* if it is a blank space that would become an undelimited parameter 427⟩;

  incr(*m*);

  if *info*(*r*) > *end_match_token* **then goto** *continue*;

  if *info*(*r*) < *match_token* **then goto** *continue*;

found: **if** $s ≠ null$ **then** ⟨Tidy up the parameter just scanned, and tuck it away 434⟩

This code is used in section 425.

427. ⟨Store the current token, but **goto** *continue* if it is a blank space that would become an undelimited parameter 427⟩ ≡
> **begin if** *cur_tok* = *space_token* **then**
>   **if** *info*(*r*) ≤ *end_match_token* **then**
>   **if** *info*(*r*) ≥ *match_token* **then goto** *continue*;
> *store_new_token*(*cur_tok*);
> **end**

This code is used in section 426.

428. A slightly subtle point arises here: When the parameter delimiter ends with '#{', the token list will have a left brace both before and after the *end_match*. Only one of these should affect the *align_state*, but both will be scanned, so we must make a correction.

⟨Advance *r*; **goto** *found* if the parameter delimiter has been fully matched, otherwise **goto** *continue* 428⟩ ≡
> **begin** *r* ← *link*(*r*);
> **if** (*info*(*r*) ≥ *match_token*) ∧ (*info*(*r*) ≤ *end_match_token*) **then**
>   **begin if** *cur_tok* < *left_brace_limit* **then** *decr*(*align_state*);
>   **goto** *found*;
>   **end**
> **else goto** *continue*;
> **end**

This code is used in section 426.

429. ⟨Report an extra right brace and **goto** *continue* 429⟩ ≡
> **begin** *back_input*; *print_err*("Argument␣of␣"); *sprint_cs*(*warning_index*); *print*("␣has␣an␣extra␣}");
> *help6*("I´ve␣run␣across␣a␣`}´␣that␣doesn´t␣seem␣to␣match␣anything.")
> ("For␣example,␣`\def\a#1{...}´␣and␣`\a}´␣would␣produce")
> ("this␣error.␣If␣you␣simply␣proceed␣now,␣the␣`\par´␣that")
> ("I´ve␣just␣inserted␣will␣cause␣me␣to␣report␣a␣runaway")
> ("argument␣that␣might␣be␣the␣root␣of␣the␣problem.␣But␣if")
> ("your␣`}´␣was␣spurious,␣just␣type␣`2´␣and␣it␣will␣go␣away."); *incr*(*align_state*);
> *long_state* ← *call*; *cur_tok* ← *par_token*; *ins_error*; **goto** *continue*;
> **end**   { a white lie; the \par won't always trigger a runaway }

This code is used in section 426.

430. If *long_state* = *outer_call*, a runaway argument has already been reported.

⟨Report a runaway argument and abort 430⟩ ≡
> **begin if** *long_state* = *call* **then**
>   **begin** *runaway*; *print_err*("Paragraph␣ended␣before␣"); *sprint_cs*(*warning_index*);
>   *print*("␣was␣complete");
>   *help3*("I␣suspect␣you´ve␣forgotten␣a␣`}´,␣causing␣me␣to␣apply␣this")
>   ("control␣sequence␣to␣too␣much␣text.␣How␣can␣we␣recover?")
>   ("My␣plan␣is␣to␣forget␣the␣whole␣thing␣and␣hope␣for␣the␣best."); *back_error*;
>   **end**;
> *pstack*[*n*] ← *link*(*temp_head*); *align_state* ← *align_state* − *unbalance*;
> **for** *m* ← 0 **to** *n* **do** *flush_list*(*pstack*[*m*]);
> **return**;
> **end**

This code is used in sections 426 and 433.

431.   When the following code becomes active, we have matched tokens from s to the predecessor of r, and we have found that $cur\_tok \neq info(r)$. An interesting situation now presents itself: If the parameter is to be delimited by a string such as 'ab', and if we have scanned 'aa', we want to contribute one 'a' to the current parameter and resume looking for a 'b'. The program must account for such partial matches and for others that can be quite complex. But most of the time we have $s = r$ and nothing needs to be done.

   Incidentally, it is possible for \par tokens to sneak in to certain parameters of non-\long macros. For example, consider a case like '\def\a#1\par!{...}' where the first \par is not followed by an exclamation point. In such situations it does not seem appropriate to prohibit the \par, so T$_{E}$X keeps quiet about this bending of the rules.

$\langle$ Contribute the recently matched tokens to the current parameter, and **goto** *continue* if a partial match is still in effect; but abort if $s = null$ 431 $\rangle \equiv$
   if $s \neq r$ **then**
      if $s = null$ **then** $\langle$ Report an improper use of the macro and abort 432 $\rangle$
      else begin $t \leftarrow s$;
         repeat $store\_new\_token(info(t))$; $incr(m)$; $u \leftarrow link(t)$; $v \leftarrow s$;
            loop begin if $u = r$ **then**
                  if $cur\_tok \neq info(v)$ **then goto** *done*
                  else begin $r \leftarrow link(v)$; **goto** *continue*;
                     end;
               if $info(u) \neq info(v)$ **then goto** *done*;
               $u \leftarrow link(u)$; $v \leftarrow link(v)$;
               end;
            done: $t \leftarrow link(t)$;
         until $t = r$;
         $r \leftarrow s$;   { at this point, no tokens are recently matched }
         end

This code is used in section 426.

432. $\langle$ Report an improper use of the macro and abort 432 $\rangle \equiv$
   begin $print\_err($"Use␣of␣"$)$; $sprint\_cs(warning\_index)$; $print($"␣doesn´t␣match␣its␣definition"$)$;
   $help4($"If␣you␣say,␣e.g.,␣`\def\a1{...}´,␣then␣you␣must␣always"$)$
   $($"put␣`1´␣after␣`\a´,␣since␣control␣sequence␣names␣are"$)$
   $($"made␣up␣of␣letters␣only.␣The␣macro␣here␣has␣not␣been"$)$
   $($"followed␣by␣the␣required␣stuff,␣so␣I´m␣ignoring␣it."$)$; $error$; **return**;
   end

This code is used in section 431.

433. $\langle$ Contribute an entire group to the current parameter 433 $\rangle \equiv$
   begin $unbalance \leftarrow 1$;
   loop begin $fast\_store\_new\_token(cur\_tok)$; get_token;
      if $cur\_tok = par\_token$ **then**
         if $long\_state \neq long\_call$ **then** $\langle$ Report a runaway argument and abort 430 $\rangle$;
      if $cur\_tok < right\_brace\_limit$ **then**
         if $cur\_tok < left\_brace\_limit$ **then** $incr(unbalance)$
         else begin $decr(unbalance)$;
            if $unbalance = 0$ **then goto** *done1*;
            end;
      end;
done1: $rbrace\_ptr \leftarrow p$; $store\_new\_token(cur\_tok)$;
   end

This code is used in section 426.

434.   If the parameter consists of a single group enclosed in braces, we must strip off the enclosing braces. That's why *rbrace_ptr* was introduced.

⟨ Tidy up the parameter just scanned, and tuck it away 434 ⟩ ≡
  begin if $(m = 1) \wedge (info(p) < right\_brace\_limit)$ **then**
    begin $link(rbrace\_ptr) \leftarrow null$; $free\_avail(p)$; $p \leftarrow link(temp\_head)$; $pstack[n] \leftarrow link(p)$; $free\_avail(p)$;
    end
  else $pstack[n] \leftarrow link(temp\_head)$;
  $incr(n)$;
  if $tracing\_macros > 0$ **then**
    begin $begin\_diagnostic$; $print\_nl(match\_chr)$; $print\_int(n)$; $print("<-")$;
    $show\_token\_list(pstack[n-1], null, 1000)$; $end\_diagnostic(false)$;
    end;
  end

This code is used in section 426.

435.   ⟨ Show the text of the macro being expanded 435 ⟩ ≡
  begin $begin\_diagnostic$; $print\_ln$; $print\_cs(warning\_index)$; $token\_show(ref\_count)$;
  $end\_diagnostic(false)$;
  end

This code is used in section 423.

436.   Basic scanning subroutines.   Let's turn now to some procedures that TEX calls upon frequently to digest certain kinds of patterns in the input. Most of these are quite simple; some are quite elaborate. Almost all of the routines call *get_x_token*, which can cause them to be invoked recursively.

437.   The *scan_left_brace* routine is called when a left brace is supposed to be the next non-blank token. (The term "left brace" means, more precisely, a character whose catcode is *left_brace*.) TEX allows \relax to appear before the *left_brace*.

procedure *scan_left_brace*;   { reads a mandatory *left_brace* }
  begin ⟨ Get the next non-blank non-relax non-call token 438 ⟩;
  if *cur_cmd* ≠ *left_brace* **then**
    begin *print_err*("Missing␣{␣inserted");
    help4("A␣left␣brace␣was␣mandatory␣here,␣so␣I´ve␣put␣one␣in.")
    ("You␣might␣want␣to␣delete␣and/or␣insert␣some␣corrections")
    ("so␣that␣I␣will␣find␣a␣matching␣right␣brace␣soon.")
    ("(If␣you´re␣confused␣by␣all␣this,␣try␣typing␣`I}´␣now.)"); *back_error*;
    cur_tok ← *left_brace_token* + "{"; *cur_cmd* ← *left_brace*; *cur_chr* ← "{"; *incr*(*align_state*);
    end;
  end;

438.   ⟨ Get the next non-blank non-relax non-call token 438 ⟩ ≡
  repeat *get_x_token*;
  until (*cur_cmd* ≠ *spacer*) ∧ (*cur_cmd* ≠ *relax*)
This code is used in sections 437, 1132, 1138, 1205, 1214, 1265, 1280, and 1324.

439.   The *scan_optional_equals* routine looks for an optional '=' sign preceded by optional spaces; '\relax' is not ignored here.

procedure *scan_optional_equals*;
  begin ⟨ Get the next non-blank non-call token 440 ⟩;
  if *cur_tok* ≠ *other_token* + "=" **then** *back_input*;
  end;

440.   ⟨ Get the next non-blank non-call token 440 ⟩ ≡
  repeat *get_x_token*;
  until *cur_cmd* ≠ *spacer*
This code is used in sections 439, 475, 490, 538, 561, 612, 1099, 1595, and 1596.

441.   In case you are getting bored, here is a slightly less trivial routine: Given a string of lowercase letters, like 'pt' or 'plus' or 'width', the *scan_keyword* routine checks to see whether the next tokens of input match this string. The match must be exact, except that uppercase letters will match their lowercase counterparts; uppercase equivalents are determined by subtracting "a" − "A", rather than using the *uc_code* table, since TEX uses this routine only for its own limited set of keywords.

 If a match is found, the characters are effectively removed from the input and *true* is returned. Otherwise *false* is returned, and the input is left essentially unchanged (except for the fact that some macros may have been expanded, etc.).

function *scan_keyword*(*s* : *str_number*): *boolean*;   { look for a given string }
  label *exit*;
  var *p*: *pointer*;   { tail of the backup list }
    q: *pointer*;   { new node being added to the token list via *store_new_token* }
    k: *pool_pointer*;   { index into *str_pool* }
    save_cur_cs: *pointer*;   { to save *cur_cs* }
  begin *p* ← *backup_head*; *link*(*p*) ← *null*;
  if *s* < *too_big_char* **then**
    begin while *true* **do**
      begin *get_x_token*;   { recursion is possible here }
      if (*cur_cs* = 0) ∧ ((*cur_chr* = *s*) ∨ (*cur_chr* = *s* − "a" + "A")) **then**
        begin *store_new_token*(*cur_tok*); *flush_list*(*link*(*backup_head*)); *scan_keyword* ← *true*; **return**;
        end
      else if (*cur_cmd* ≠ *spacer*) ∨ (*p* ≠ *backup_head*) **then**
          begin *back_input*;
          if *p* ≠ *backup_head* **then** *back_list*(*link*(*backup_head*));
          scan_keyword ← *false*; **return**;
          end;
      end;
    end;
  k ← *str_start_macro*(*s*); *save_cur_cs* ← *cur_cs*;
  while *k* < *str_start_macro*(*s* + 1) **do**
    begin *get_x_token*;   { recursion is possible here }
    if (*cur_cs* = 0) ∧ ((*cur_chr* = *so*(*str_pool*[*k*])) ∨ (*cur_chr* = *so*(*str_pool*[*k*]) − "a" + "A")) **then**
      begin *store_new_token*(*cur_tok*); *incr*(*k*);
      end
    else if (*cur_cmd* ≠ *spacer*) ∨ (*p* ≠ *backup_head*) **then**
        begin *back_input*;
        if *p* ≠ *backup_head* **then** *back_list*(*link*(*backup_head*));
        cur_cs ← *save_cur_cs*; *scan_keyword* ← *false*; **return**;
        end;
    end;
  flush_list(*link*(*backup_head*)); *scan_keyword* ← *true*;
exit: **end**;

442.   Here is a procedure that sounds an alarm when mu and non-mu units are being switched.

procedure *mu_error*;
  begin *print_err*("Incompatible␣glue␣units");
  help1("I´m␣going␣to␣assume␣that␣1mu=1pt␣when␣they´re␣mixed."); *error*;
  end;

443.   The next routine '*scan_something_internal*' is used to fetch internal numeric quantities like '\hsize', and also to handle the '\the' when expanding constructions like '\the\toks0' and '\the\baselineskip'. Soon we will be considering the *scan_int* procedure, which calls *scan_something_internal*; on the other hand, *scan_something_internal* also calls *scan_int*, for constructions like '\catcode`\$' or '\fontdimen 3 \ff'. So we have to declare *scan_int* as a *forward* procedure. A few other procedures are also declared at this point.

procedure *scan_int*; *forward*;   { scans an integer value }
⟨ Declare procedures that scan restricted classes of integers 467 ⟩
⟨ Declare ε-TEX procedures for scanning 1492 ⟩
⟨ Declare procedures that scan font-related stuff 612 ⟩

444.   TEX doesn't know exactly what to expect when *scan_something_internal* begins. For example, an integer or dimension or glue value could occur immediately after '\hskip'; and one can even say \the with respect to token lists in constructions like '\xdef\o{\the\output}'. On the other hand, only integers are allowed after a construction like '\count'. To handle the various possibilities, *scan_something_internal* has a *level* parameter, which tells the "highest" kind of quantity that *scan_something_internal* is allowed to produce. Six levels are distinguished, namely *int_val*, *dimen_val*, *glue_val*, *mu_val*, *ident_val*, and *tok_val*.

The output of *scan_something_internal* (and of the other routines *scan_int*, *scan_dimen*, and *scan_glue* below) is put into the global variable *cur_val*, and its level is put into *cur_val_level*. The highest values of *cur_val_level* are special: *mu_val* is used only when *cur_val* points to something in a "muskip" register, or to one of the three parameters \thinmuskip, \medmuskip, \thickmuskip; *ident_val* is used only when *cur_val* points to a font identifier; *tok_val* is used only when *cur_val* points to *null* or to the reference count of a token list. The last two cases are allowed only when *scan_something_internal* is called with *level* = *tok_val*.

If the output is glue, *cur_val* will point to a glue specification, and the reference count of that glue will have been updated to reflect this reference; if the output is a nonempty token list, *cur_val* will point to its reference count, but in this case the count will not have been updated. Otherwise *cur_val* will contain the integer or scaled value in question.

define *int_val* = 0   { integer values }
define *dimen_val* = 1   { dimension values }
define *glue_val* = 2   { glue specifications }
define *mu_val* = 3   { math glue specifications }
define *ident_val* = 4   { font identifier }
define *tok_val* = 5   { token lists }
define *inter_char_val* = 6   { inter-character (class) token lists }

⟨ Global variables 13 ⟩ +≡
cur_val: *integer*;   { value returned by numeric scanners }
cur_val1: *integer*;   { value returned by numeric scanners }
cur_val_level: *int_val* .. *tok_val*;   { the "level" of this value }

445.   The hash table is initialized with '\count', '\dimen', '\skip', and '\muskip' all having *register* as their command code; they are distinguished by the *chr_code*, which is either *int_val*, *dimen_val*, *glue_val*, or *mu_val* more than *mem_bot* (dynamic variable-size nodes cannot have these values)

⟨ Put each of TEX's primitives into the hash table 252 ⟩ +≡
  primitive("count", *register*, *mem_bot* + *int_val*); *primitive*("dimen", *register*, *mem_bot* + *dimen_val*);
  primitive("skip", *register*, *mem_bot* + *glue_val*); *primitive*("muskip", *register*, *mem_bot* + *mu_val*);

446.   ⟨ Cases of *print_cmd_chr* for symbolic printing of primitives 253 ⟩ +≡
register: ⟨ Cases of *register* for *print_cmd_chr* 1643 ⟩;

447.   OK, we're ready for *scan_something_internal* itself. A second parameter, *negative*, is set *true* if the value that is found should be negated. It is assumed that *cur_cmd* and *cur_chr* represent the first token of the internal quantity to be scanned; an error will be signalled if *cur_cmd* < *min_internal* or *cur_cmd* > *max_internal*.

> **define** *scanned_result_end*(#) ≡ *cur_val_level* ← #; **end**
> **define** *scanned_result*(#) ≡ **begin** *cur_val* ← #; *scanned_result_end*

450. Users refer to '\the\spacefactor' only in horizontal mode, and to '\the\prevdepth' only in vertical mode; so we put the associated mode in the modifier part of the *set_aux* command. The *set_page_int* command has modifier 0 or 1, for '\deadcycles' and '\insertpenalties', respectively. The *set_box_dimen* command is modified by either *width_offset*, *height_offset*, or *depth_offset*. And the *last_item* command is modified by either *int_val*, *dimen_val*, *glue_val*, *input_line_no_code*, or *badness_code*. ε-TEX inserts *last_node_type_code* after *glue_val* and adds the codes for its extensions: *eTeX_version_code*, ...

> **define** *last_node_type_code* = *glue_val* + 1   { code for \lastnodetype }
> **define** *input_line_no_code* = *glue_val* + 2   { code for \inputlineno }

472. An integer number can be preceded by any number of spaces and '+' or '−' signs. Then comes either a decimal constant (i.e., radix 10), an octal constant (i.e., radix 8, preceded by ´), a hexadecimal constant (radix 16, preceded by "), an alphabetic constant (preceded by `), or an internal variable. After scanning is complete, *cur_val* will contain the answer, which must be at most $2^{31} - 1 = 2147483647$ in absolute value. The value of *radix* is set to 10, 8, or 16 in the cases of decimal, octal, or hexadecimal constants, otherwise *radix* is set to zero. An optional space follows a constant.

  define *octal_token* = *other_token* + "´"   { apostrophe, indicates an octal constant }
  define *hex_token* = *other_token* + """"   { double quote, indicates a hex constant }
  define *alpha_token* = *other_token* + "`"   { reverse apostrophe, precedes alpha constants }
  define *point_token* = *other_token* + "."   { decimal point }
  define *continental_point_token* = *other_token* + ","   { decimal point, Eurostyle }

⟨Global variables 13⟩ +≡
radix: *small_number*;   { *scan_int* sets this to 8, 10, 16, or zero }

473. We initialize the following global variables just in case *expand* comes into action before any of the basic scanning routines has assigned them a value.

⟨Set initial values of key variables 23⟩ +≡
  cur_val ← 0; *cur_val_level* ← *int_val*; *radix* ← 0; *cur_order* ← *normal*;

474. The *scan_int* routine is used also to scan the integer part of a fraction; for example, the '3' in '3.14159' will be found by *scan_int*. The *scan_dimen* routine assumes that *cur_tok* = *point_token* after the integer part of such a fraction has been scanned by *scan_int*, and that the decimal point has been backed up to be scanned again.

procedure *scan_int*;   { sets *cur_val* to an integer }
  label *done*, *restart*;

  end

This code is used in section 478.

481.   The *scan_dimen* routine is similar to *scan_int*, but it sets *cur_val* to a *scaled* value, i.e., an integral number of sp. One of its main tasks is therefore to interpret the abbreviations for various kinds of units and to convert measurements to scaled points.

There are three parameters: *mu* is *true* if the finite units must be 'mu', while *mu* is *false* if 'mu' units are disallowed; *inf* is *true* if the infinite units 'fil', 'fill', 'filll' are permitted; and *shortcut* is *true* if *cur_val* already contains an integer and only the units need to be considered.

The order of infinity that was found in the case of infinite glue is returned in the global variable *cur_order*.

⟨ Global variables 13 ⟩ +≡
cur_order: *glue_ord*;   { order of infinity found by *scan_dimen* }

482. Constructions like '−´77 pt' are legal dimensions, so *scan_dimen* may begin with *scan_int*. This explains why it is convenient to use *scan_int* also for the integer part of a decimal fraction.

Several branches of *scan_dimen* work with *cur_val* as an integer and with an auxiliary fraction f, so that the actual quantity of interest is $cur\_val + f/2^{16}$. At the end of the routine, this "unpacked" representation is put into the single word *cur_val*, which suddenly switches significance from *integer* to *scaled*.

> **define** *attach_fraction* = 88   { go here to pack *cur_val* and f into *cur_val* }
> **define** *attach_sign* = 89   { go here when *cur_val* is correct except perhaps for sign }

  end

This code is used in section 482.

496.   The final member of TEX's value-scanning trio is *scan_glue*, which makes *cur_val* point to a glue specification. The reference count of that glue spec will take account of the fact that *cur_val* is pointing to it.

The *level* parameter should be either *glue_val* or *mu_val*.

Since *scan_dimen* was so much more complex than *scan_int*, we might expect *scan_glue* to be even worse. But fortunately, it is very simple, since most of the work has already been done.

procedure *scan_glue*(*level* : *small_number*);   { sets *cur_val* to a glue spec pointer }
  label *exit*;
  var *negative*: *boolean*;   { should the answer be negated? }
    q: *pointer*;   { new glue specification }
    mu: *boolean*;   { does *level* = *mu_val*? }

    begin *scan_dimen*(*mu*, *true*, *false*); *shrink*(*q*) ← *cur_val*; *shrink_order*(*q*) ← *cur_order*;
    end;
  cur_val ← *q*

This code is used in section 496.

498.   Here's a similar procedure that returns a pointer to a rule node. This routine is called just after TEX
has seen \hrule or \vrule; therefore *cur_cmd* will be either *hrule* or *vrule*. The idea is to store the default
rule dimensions in the node, then to override them if 'height' or 'width' or 'depth' specifications are found
(in any order).

> **define** *default_rule* = 26214   { 0.4 pt }

function *scan_rule_spec*: *pointer*;
  label *reswitch*;
  var *q*: *pointer*;   { the rule node being created }
  begin *q* ← *new_rule*;   { *width*, *depth*, and *height* all equal *null_flag* now }
  if *cur_cmd* = *vrule* **then** *width*(*q*) ← *default_rule*
  else begin *height*(*q*) ← *default_rule*; *depth*(*q*) ← 0;
    end;
reswitch: **if** *scan_keyword*("width") **then**
    begin *scan_normal_dimen*; *width*(*q*) ← *cur_val*; **goto** *reswitch*;
    end;
  if *scan_keyword*("height") **then**
    begin *scan_normal_dimen*; *height*(*q*) ← *cur_val*; **goto** *reswitch*;
    end;
  if *scan_keyword*("depth") **then**
    begin *scan_normal_dimen*; *depth*(*q*) ← *cur_val*; **goto** *reswitch*;
    end;
  scan_rule_spec ← *q*;
  end;

499.   Building token lists.   The token lists for macros and for other things like \mark and \output and \write are produced by a procedure called *scan_toks*.

Before we get into the details of *scan_toks*, let's consider a much simpler task, that of converting the current string into a token list. The *str_toks* function does this; it classifies spaces as type *spacer* and everything else as type *other_char*.

The token list created by *str_toks* begins at *link*(*temp_head*) and ends at the value *p* that is returned. (If *p* = *temp_head*, the list is empty.)

The *str_toks_cat* function is the same, except that the catcode *cat* is stamped on all the characters, unless zero is passed in which case it chooses *spacer* or *other_char* automatically.

⟨ Declare ε-T_EX procedures for token lists 1493 ⟩
function *str_toks_cat*(*b* : *pool_pointer*; *cat* : *small_number*): *pointer*;
        { changes the string *str_pool*[*b* . . *pool_ptr*] to a token list }
  var *p*: *pointer*;   { tail of the token list }
    q: *pointer*;   { new node being added to the token list via *store_new_token* }
    t: *halfword*;   { token being appended }
    k: *pool_pointer*;   { index into *str_pool* }
  begin *str_room*(1); *p* ← *temp_head*; *link*(*p*) ← *null*; *k* ← *b*;
  while *k* < *pool_ptr* **do**
    begin *t* ← *so*(*str_pool*[*k*]);
    if (*t* = "␣") ∧ (*cat* = 0) **then** *t* ← *space_token*
    else begin if (*t* ≥ ″D800) ∧ (*t* ≤ ″DBFF) ∧ (*k* + 1 < *pool_ptr*) ∧ (*so*(*str_pool*[*k* + 1]) ≥
            ″DC00) ∧ (*so*(*str_pool*[*k* + 1]) ≤ ″DFFF) **then**
      begin *incr*(*k*); *t* ← ″10000 + (*t* − ″D800) ∗ ″400 + (*so*(*str_pool*[*k*]) − ″DC00);
      end;
    if *cat* = 0 **then** *t* ← *other_token* + *t*
    else if *cat* = *active_char* **then** *t* ← *cs_token_flag* + *active_base* + *t*
      else *t* ← *max_char_val* ∗ *cat* + *t*;
    end;
    fast_store_new_token(*t*); *incr*(*k*);
    end;
  pool_ptr ← *b*; *str_toks_cat* ← *p*;
  end;
function *str_toks*(*b* : *pool_pointer*): *pointer*;
  begin *str_toks* ← *str_toks_cat*(*b*, 0);
  end;

500.   The main reason for wanting *str_toks* is the next function, *the_toks*, which has similar input/output characteristics.

This procedure is supposed to scan something like '\skip\count12', i.e., whatever can follow '\the', and it constructs a token list containing something like '-3.0pt minus 0.5fill'.

function *the_toks*: *pointer*;
  label *exit*;
  var *old_setting*: 0 .. *max_selector*;   { holds *selector* setting }
    p, q, r: *pointer*;   { used for copying a token list }
    b: *pool_pointer*;   { base of temporary string }
    c: *small_number*;   { value of *cur_chr* }
  begin ⟨ Handle \unexpanded or \detokenize and **return** 1498 ⟩;
  get_x_token; *scan_something_internal*(*tok_val*, *false*);
  if *cur_val_level* ≥ *ident_val* **then** ⟨ Copy the token list 501 ⟩
  else begin *old_setting* ← *selector*; *selector* ← *new_string*; *b* ← *pool_ptr*;
    case *cur_val_level* **of**
    int_val: *print_int*(*cur_val*);
    dimen_val: **begin** *print_scaled*(*cur_val*); *print*("pt");
      end;
    glue_val: **begin** *print_spec*(*cur_val*, "pt"); *delete_glue_ref*(*cur_val*);
      end;
    mu_val: **begin** *print_spec*(*cur_val*, "mu"); *delete_glue_ref*(*cur_val*);
      end;
    end;   { there are no other cases }
    selector ← *old_setting*; *the_toks* ← *str_toks*(*b*);
    end;
exit: **end**;

501.   ⟨ Copy the token list 501 ⟩ ≡
  begin *p* ← *temp_head*; *link*(*p*) ← *null*;
  if *cur_val_level* = *ident_val* **then** *store_new_token*(*cs_token_flag* + *cur_val*)
  else if *cur_val* ≠ *null* **then**
    begin *r* ← *link*(*cur_val*);   { do not copy the reference count }
    while *r* ≠ *null* **do**
      begin *fast_store_new_token*(*info*(*r*)); *r* ← *link*(*r*);
      end;
    end;
  the_toks ← *p*;
  end

This code is used in section 500.

502.   Here's part of the *expand* subroutine that we are now ready to complete:

procedure *ins_the_toks*;
  begin *link*(*garbage*) ← *the_toks*; *ins_list*(*link*(*temp_head*));
  end;

505. The procedure *conv_toks* uses *str_toks* to insert the token list for *convert* functions into the scanner; '\outer' control sequences are allowed to follow '\string' and '\meaning'.

The extra temp string u is needed because *pdf_scan_ext_toks* incorporates any pending string in its output. In order to save such a pending string, we have to create a temporary string that is destroyed immediately after.

> **define** *save_cur_string* ≡

508.   Now we can't postpone the difficulties any longer; we must bravely tackle *scan_toks*. This function returns a pointer to the tail of a new token list, and it also makes *def_ref* point to the reference count at the head of that list.

There are two boolean parameters, *macro_def* and *xpand*. If *macro_def* is true, the goal is to create the token list for a macro definition; otherwise the goal is to create the token list for some other TEX primitive: \mark, \output, \everypar, \lowercase, \uppercase, \message, \errmessage, \write, or \special. In the latter cases a left brace must be scanned next; this left brace will not be part of the token list, nor will the matching right brace that comes at the end. If *xpand* is false, the token list will simply be copied from the input using *get_token*. Otherwise all expandable tokens will be expanded until unexpandable tokens are left, except that the results of expanding '\the' are not expanded further. If both *macro_def* and *xpand* are true, the expansion applies only to the macro body (i.e., to the material following the first *left_brace* character).

The value of *cur_cs* when *scan_toks* begins should be the *eqtb* address of the control sequence to display in "runaway" error messages.

  othercases *print_esc*("if")

  endcases;

  end;

524. Conditions can be inside conditions, and this nesting has a stack that is independent of the *save_stack*.

Four global variables represent the top of the condition stack: *cond_ptr* points to pushed-down entries, if any; *if_limit* specifies the largest code of a *fi_or_else* command that is syntactically legal; *cur_if* is the name of the current type of conditional; and *if_line* is the line number at which it began.

If no conditions are currently in progress, the condition stack has the special state *cond_ptr* = *null*, *if_limit* = *normal*, *cur_if* = 0, *if_line* = 0. Otherwise *cond_ptr* points to a two-word node; the *type*, *subtype*, and *link* fields of the first word contain *if_limit*, *cur_if*, and *cond_ptr* at the next level, and the second word contains the corresponding *if_line*.

  define *if_node_size* = 2   {number of words in stack entry for conditionals}

  define *if_line_field*(#) ≡ *mem*[# + 1].*int*

  define *if_code* = 1   {code for \if... being evaluated}

  define *fi_code* = 2   {code for \fi}

  define *else_code* = 3   {code for \else}

  define *or_code* = 4   {code for \or}

⟨Global variables 13⟩ +≡

cond_ptr: *pointer*;   {top of the condition stack}

if_limit: *normal* .. *or_code*;   {upper bound on *fi_or_else* codes}

cur_if: *small_number*;   {type of conditional being worked on}

if_line: *integer*;   {line where that conditional began}

525. ⟨Set initial values of key variables 23⟩ +≡

  cond_ptr ← *null*; *if_limit* ← *normal*; *cur_if* ← 0; *if_line* ← 0;

526. ⟨Put each of TEX's primitives into the hash table 252⟩ +≡

  primitive("fi", *fi_or_else*, *fi_code*); *text*(*frozen_fi*) ← "fi"; *eqtb*[*frozen_fi*] ← *eqtb*[*cur_val*];

  primitive("or", *fi_or_else*, *or_code*); *primitive*("else", *fi_or_else*, *else_code*);

527. ⟨Cases of *print_cmd_chr* for symbolic printing of primitives 253⟩ +≡
fi_or_else: **if** *chr_code* = *fi_code* **then** *print_esc*("fi")
   else if *chr_code* = *or_code* **then** *print_esc*("or")
      else *print_esc*("else");

528. When we skip conditional text, we keep track of the line number where skipping began, for use in error messages.

⟨Global variables 13⟩ +≡
skip_line: *integer*;   {skipping began here}

529. Here is a procedure that ignores text until coming to an \or, \else, or \fi at the current level of \if . . . \fi nesting. After it has acted, *cur_chr* will indicate the token that was found, but *cur_tok* will not be set (because this makes the procedure run faster).

procedure *pass_text*;
   label *done*;
   var *l*: *integer*;   {level of \if . . . \fi nesting}
      save_scanner_status: *small_number*;   {*scanner_status* upon entry}
   begin *save_scanner_status* ← *scanner_status*; *scanner_status* ← *skipping*; *l* ← 0; *skip_line* ← *line*;
   loop begin *get_next*;
      if *cur_cmd* = *fi_or_else* **then**
         begin if *l* = 0 **then goto** *done*;
         if *cur_chr* = *fi_code* **then** *decr*(*l*);
         end
      else if *cur_cmd* = *if_test* **then** *incr*(*l*);
      end;
done: *scanner_status* ← *save_scanner_status*;
   if *tracing_ifs* > 0 **then** *show_cur_cmd_chr*;
   end;

530. When we begin to process a new \if, we set *if_limit* ← *if_code*; then if \or or \else or \fi occurs before the current \if condition has been evaluated, \relax will be inserted. For example, a sequence of commands like '\ifvoid1\else...\fi' would otherwise require something after the '1'.

⟨Push the condition stack 530⟩ ≡
   begin *p* ← *get_node*(*if_node_size*); *link*(*p*) ← *cond_ptr*; *type*(*p*) ← *if_limit*; *subtype*(*p*) ← *cur_if*;
   if_line_field(*p*) ← *if_line*; *cond_ptr* ← *p*; *cur_if* ← *cur_chr*; *if_limit* ← *if_code*; *if_line* ← *line*;
   end
This code is used in section 533.

531. ⟨Pop the condition stack 531⟩ ≡
   begin if *if_stack*[*in_open*] = *cond_ptr* **then** *if_warning*;
         {conditionals possibly not properly nested with files}
   p ← *cond_ptr*; *if_line* ← *if_line_field*(*p*); *cur_if* ← *subtype*(*p*); *if_limit* ← *type*(*p*); *cond_ptr* ← *link*(*p*);
   free_node(*p*, *if_node_size*);
   end
This code is used in sections 533, 535, 544, and 545.

532. Here's a procedure that changes the *if_limit* code corresponding to a given value of *cond_ptr*.

procedure *change_if_limit*(*l* : *small_number*; *p* : *pointer*);
  label *exit*;
  var *q*: *pointer*;
  begin if *p* = *cond_ptr* **then** *if_limit* ← *l*   { that's the easy case }
  else begin *q* ← *cond_ptr*;
    loop begin if *q* = *null* **then** *confusion*("if");
      if *link*(*q*) = *p* **then**
        begin *type*(*q*) ← *l*; **return**;
        end;
      q ← *link*(*q*);
      end;
    end;
exit: **end**;

533. A condition is started when the *expand* procedure encounters an *if_test* command; in that case *expand* reduces to *conditional*, which is a recursive procedure.

procedure *conditional*;
  label *exit*, *common_ending*;
  var *b*: *boolean*;   { is the condition true? }
    e: *boolean*;   { keep track of nested csnames }
    r: "<" .. ">";   { relation to be evaluated }
    m, *n*: *integer*;   { to be tested against the second operand }
    p, *q*: *pointer*;   { for traversing token lists in \ifx tests }
    save_scanner_status: *small_number*;   { *scanner_status* upon entry }
    save_cond_ptr: *pointer*;   { *cond_ptr* corresponding to this conditional }
    this_if: *small_number*;   { type of this conditional }
    is_unless: *boolean*;   { was this if preceded by '\unless' ? }
  begin if *tracing_ifs* > 0 **then**
    if *tracing_commands* ≤ 1 **then** *show_cur_cmd_chr*;
  ⟨Push the condition stack 530⟩; *save_cond_ptr* ← *cond_ptr*; *is_unless* ← (*cur_chr* ≥ *unless_code*);
  this_if ← *cur_chr* **mod** *unless_code*;
  ⟨Either process \ifcase or set *b* to the value of a boolean condition 536⟩;
  if *is_unless* **then** *b* ← ¬*b*;
  if *tracing_commands* > 1 **then** ⟨Display the value of *b* 537⟩;
  if *b* **then**
    begin *change_if_limit*(*else_code*, *save_cond_ptr*); **return**;   { wait for \else or \fi }
    end;
  ⟨Skip to \else or \fi, then **goto** *common_ending* 535⟩;
common_ending: **if** *cur_chr* = *fi_code* **then** ⟨Pop the condition stack 531⟩
  else *if_limit* ← *fi_code*;   { wait for \fi }
exit: **end**;

534. In a construction like '\if\iftrue abc\else d\fi', the first \else that we come to after learning that the \if is false is not the \else we're looking for. Hence the following curious logic is needed.

535. ⟨Skip to \else or \fi, then **goto** *common_ending* 535⟩ ≡
  loop begin *pass_text*;
    if *cond_ptr* = *save_cond_ptr* **then**

  ">": *b* ← (*n* > *cur_val*);
  end;
  end

This code is used in section 536.

539.   ⟨Test if an integer is odd 539⟩ ≡
  begin *scan_int*; *b* ← *odd*(*cur_val*);
  end

This code is used in section 536.

540.   ⟨Test box register status 540⟩ ≡
  begin *scan_register_num*; *fetch_box*(*p*);
  if *this_if* = *if_void_code* **then** *b* ← (*p* = *null*)
  else if *p* = *null* **then** *b* ← *false*
    else if *this_if* = *if_hbox_code* **then** *b* ← (*type*(*p*) = *hlist_node*)
      else *b* ← (*type*(*p*) = *vlist_node*);
  end

This code is used in section 536.

541. An active character will be treated as category 13 following `\if\noexpand` or following `\ifcat\noexpand`. We use the fact that active characters have the smallest tokens, among all control sequences.

> **define** $get\_x\_token\_or\_active\_char \equiv$
>> **begin** get_x_token;
>> **if** $cur\_cmd = relax$ **then**
>>> **if** $cur\_chr = no\_expand\_flag$ **then**
>>>> **begin** $cur\_cmd \leftarrow active\_char$; $cur\_chr \leftarrow cur\_tok - cs\_token\_flag - active\_base$;
>>>> **end**;
>> **end**

⟨ Test if two characters match 541 ⟩ ≡
> **begin** $get\_x\_token\_or\_active\_char$;
> **if** $(cur\_cmd > active\_char) \vee (cur\_chr > biggest\_usv)$ **then**   { not a character }
>> **begin** $m \leftarrow relax$; $n \leftarrow too\_big\_usv$;
>> **end**
> **else begin** $m \leftarrow cur\_cmd$; $n \leftarrow cur\_chr$;
>> **end**;
> $get\_x\_token\_or\_active\_char$;
> **if** $(cur\_cmd > active\_char) \vee (cur\_chr > biggest\_usv)$ **then**
>> **begin** $cur\_cmd \leftarrow relax$; $cur\_chr \leftarrow too\_big\_usv$;
>> **end**;
> **if** $this\_if = if\_char\_code$ **then** $b \leftarrow (n = cur\_chr)$ **else** $b \leftarrow (m = cur\_cmd)$;
> **end**

This code is used in section 536.

542. Note that '`\ifx`' will declare two macros different if one is *long* or *outer* and the other isn't, even though the texts of the macros are the same.

We need to reset *scanner_status*, since `\outer` control sequences are allowed, but we might be scanning a macro definition or preamble.

⟨ Test if two tokens match 542 ⟩ ≡
> **begin** $save\_scanner\_status \leftarrow scanner\_status$; $scanner\_status \leftarrow normal$; get_next; $n \leftarrow cur\_cs$;
> $p \leftarrow cur\_cmd$; $q \leftarrow cur\_chr$; get_next;
> **if** $cur\_cmd \neq p$ **then** $b \leftarrow false$
> **else if** $cur\_cmd < call$ **then** $b \leftarrow (cur\_chr = q)$
>> **else** ⟨ Test if two macro texts match 543 ⟩;
> $scanner\_status \leftarrow save\_scanner\_status$;
> **end**

This code is used in section 536.

543.   Note also that '\ifx' decides that macros \a and \b are different in examples like this:

$$\def\a{\c}   \def\c{}$$
$$\def\b{\d}   \def\d{}$$

⟨ Test if two macro texts match 543 ⟩ ≡
  begin $p \leftarrow link(cur\_chr)$; $q \leftarrow link(equiv(n))$;   { omit reference counts }
  if $p = q$ **then** $b \leftarrow true$
  else begin while $(p \neq null) \wedge (q \neq null)$ **do**
      if $info(p) \neq info(q)$ **then** $p \leftarrow null$
      else begin $p \leftarrow link(p)$; $q \leftarrow link(q)$;
        end;
    $b \leftarrow ((p = null) \wedge (q = null))$;
    end;
  end

This code is used in section 542.

544.   ⟨ Select the appropriate case and **return** or **goto** *common_ending* 544 ⟩ ≡
  begin $scan\_int$; $n \leftarrow cur\_val$;   { n is the number of cases to pass }
  if $tracing\_commands > 1$ **then**
    begin $begin\_diagnostic$; $print("\{case_{\sqcup}")$; $print\_int(n)$; $print\_char("\}")$; $end\_diagnostic(false)$;
    end;
  while $n \neq 0$ **do**
    begin $pass\_text$;
    if $cond\_ptr = save\_cond\_ptr$ **then**
      if $cur\_chr = or\_code$ **then** $decr(n)$
      else goto *common_ending*
    else if $cur\_chr = fi\_code$ **then** ⟨ Pop the condition stack 531 ⟩;
    end;
  $change\_if\_limit(or\_code, save\_cond\_ptr)$; **return**;   { wait for \or, \else, or \fi }
  end

This code is used in section 536.

545.   The processing of conditionals is complete except for the following code, which is actually part of *expand*. It comes into play when \or, \else, or \fi is scanned.

⟨ Terminate the current conditional and skip to \fi 545 ⟩ ≡
  begin if $tracing\_ifs > 0$ **then**
    if $tracing\_commands \leq 1$ **then** $show\_cur\_cmd\_chr$;
  if $cur\_chr > if\_limit$ **then**
    if $if\_limit = if\_code$ **then** $insert\_relax$ { condition not yet evaluated }
    else begin $print\_err("Extra_{\sqcup}")$; $print\_cmd\_chr(fi\_or\_else, cur\_chr)$;
      $help1("I´m_{\sqcup}ignoring_{\sqcup}this;_{\sqcup}it_{\sqcup}doesn´t_{\sqcup}match_{\sqcup}any_{\sqcup}\if.")$; $error$;
      end
  else begin while $cur\_chr \neq fi\_code$ **do** $pass\_text$;   { skip to \fi }
    ⟨ Pop the condition stack 531 ⟩;
    end;
  end

This code is used in section 399.

546. File names. It's time now to fret about file names. Besides the fact that different operating systems treat files in different ways, we must cope with the fact that completely different naming conventions are used by different groups of people. The following programs show what is required for one particular operating system; similar routines for other systems are not difficult to devise.

TEX assumes that a file name has three parts: the name proper; its "extension"; and a "file area" where it is found in an external file system. The extension of an input file or a write file is assumed to be '`.tex`' unless otherwise specified; it is '`.log`' on the transcript file that records each run of TEX; it is '`.tfm`' on the font metric files that describe characters in the fonts TEX uses; it is '`.dvi`' on the output files that specify typesetting information; and it is '`.fmt`' on the format files written by `INITEX` to initialize TEX. The file area can be arbitrary on input files, but files are usually output to the user's current area. If an input file cannot be found on the specified area, TEX will look for it on a special system area; this special area is intended for commonly used input files like `webmac.tex`.

Simple uses of TEX refer only to file names that have no explicit extension or area. For example, a person usually says '`\input paper`' or '`\font\tenrm = helvetica`' instead of '`\input paper.new`' or '`\font\tenrm = <csd.knuth>test`'. Simple file names are best, because they make the TEX source files portable; whenever a file name consists entirely of letters and digits, it should be treated in the same way by all implementations of TEX. However, users need the ability to refer to other files in their environment, especially when responding to error messages concerning unopenable files; therefore we want to let them use the syntax that appears in their favorite operating system.

547. In order to isolate the system-dependent aspects of file names, the system-independent parts of TEX are expressed in terms of three system-dependent procedures called *begin_name*, *more_name*, and *end_name*. In essence, if the user-specified characters of the file name are $c_1 \ldots c_n$, the system-independent driver program does the operations

$$begin\_name; \ more\_name(c_1); \ \ldots; \ more\_name(c_n); \ end\_name.$$

These three procedures communicate with each other via global variables. Afterwards the file name will appear in the string pool as three strings called *cur_name*, *cur_area*, and *cur_ext*; the latter two are null (i.e., `""`), unless they were explicitly specified by the user.

Actually the situation is slightly more complicated, because TEX needs to know when the file name ends. The *more_name* routine is a function (with side effects) that returns *true* on the calls $more\_name(c_1)$, ..., $more\_name(c_{n-1})$. The final call $more\_name(c_n)$ returns *false*; or, it returns *true* and the token following c_n is something like '`\hbox`' (i.e., not a character). In other words, *more_name* is supposed to return *true* unless it is sure that the file name has been completely scanned; and *end_name* is supposed to be able to finish the assembly of *cur_name*, *cur_area*, and *cur_ext* regardless of whether $more\_name(c_n)$ returned *true* or *false*.

⟨ Global variables 13 ⟩ +≡
cur_name: *str_number*;   { name of file just scanned }
cur_area: *str_number*;   { file area just scanned, or `""` }
cur_ext: *str_number*;   { file extension just scanned, or `""` }

548. The file names we shall deal with for illustrative purposes have the following structure: If the name contains '`>`' or '`:`', the file area consists of all characters up to and including the final such character; otherwise the file area is null. If the remaining file name contains '`.`', the file extension consists of all such characters from the first remaining '`.`' to the end, otherwise the file extension is null.

We can scan such file names easily by using two global variables that keep track of the occurrences of area and extension delimiters:

⟨ Global variables 13 ⟩ +≡
area_delimiter: *pool_pointer*;   { the most recent '`>`' or '`:`', if any }
ext_delimiter: *pool_pointer*;   { the relevant '`.`', if any }
file_name_quote_char: *UTF16_code*;

549. Input files that can't be found in the user's area may appear in a standard system area called *TEX_area*. Font metric files whose areas are not given explicitly are assumed to appear in a standard system area called *TEX_font_area*. These system area names will, of course, vary from place to place.

> **define** *TEX_area* ≡ `"TeXinputs:"`
> **define** *TEX_font_area* ≡ `"TeXfonts:"`

550. Here now is the first of the system-dependent routines for file name scanning.

procedure *begin_name*;
  begin *area_delimiter* ← 0; *ext_delimiter* ← 0; *file_name_quote_char* ← 0;
  end;

551. And here's the second. The string pool might change as the file name is being scanned, since a new \csname might be entered; therefore we keep *area_delimiter* and *ext_delimiter* relative to the beginning of the current string, instead of assigning an absolute address like *pool_ptr* to them.

function *more_name*(*c* : *UnicodeScalar*): *boolean*;
  begin if *c* = `"␣"` **then** *more_name* ← *false*
  else begin if (*c* > ″FFFF) **then** *str_room*(2)
    else *str_room*(1);
    append_char(*c*);   { contribute *c* to the current string }
    if (*c* = `">"`) ∨ (*c* = `":"`) **then**
      begin *area_delimiter* ← *cur_length*; *ext_delimiter* ← 0;
      end
    else if (*c* = `"."`) ∧ (*ext_delimiter* = 0) **then** *ext_delimiter* ← *cur_length*;
    more_name ← *true*;
    end;
  end;

552. The third.

procedure *end_name*;
  begin if *str_ptr* + 3 > *max_strings* **then** *overflow*(`"number␣of␣strings"`, *max_strings* − *init_str_ptr*);
  if *area_delimiter* = 0 **then** *cur_area* ← `""`
  else begin *cur_area* ← *str_ptr*; *str_start_macro*(*str_ptr* + 1) ← *str_start_macro*(*str_ptr*) + *area_delimiter*;
    incr(*str_ptr*);
    end;
  if *ext_delimiter* = 0 **then**
    begin *cur_ext* ← `""`; *cur_name* ← *make_string*;
    end
  else begin *cur_name* ← *str_ptr*;
    str_start_macro(*str_ptr* + 1) ← *str_start_macro*(*str_ptr*) + *ext_delimiter* − *area_delimiter* − 1;
    incr(*str_ptr*); *cur_ext* ← *make_string*;
    end;
  end;

553. Conversely, here is a routine that takes three strings and prints a file name that might have produced them. (The routine is system dependent, because some operating systems put the file area last instead of first.)

⟨ Basic printing procedures 57 ⟩ +≡
procedure *print_file_name*(*n*, *a*, *e* : *integer*);
  begin *slow_print*(*a*); *slow_print*(*n*); *slow_print*(*e*);
  end;

554. Another system-dependent routine is needed to convert three internal T$_{E}$X strings into the *name_of_file* value that is used to open files. The present code allows both lowercase and uppercase letters in the file name.

> **define** *append_to_name*(#) ≡
>   **begin** $c \leftarrow$ #; *incr*(k);
>   **if** $k \leq$ *file_name_size* **then** *name_of_file*[k] $\leftarrow$ *xchr*[c];
>   **end**

procedure *pack_file_name*(n, a, e : *str_number*);
>   **var** k: *integer*;   {number of positions filled in *name_of_file*}
> c: *UnicodeScalar*;   {character being packed}
> j: *pool_pointer*;   {index into *str_pool*}
>   **begin** $k \leftarrow 0$;
>   **for** $j \leftarrow$ *str_start_macro*(a) **to** *str_start_macro*($a + 1$) $- 1$ **do** *append_to_name*(*so*(*str_pool*[j]));
>   **for** $j \leftarrow$ *str_start_macro*(n) **to** *str_start_macro*($n + 1$) $- 1$ **do** *append_to_name*(*so*(*str_pool*[j]));
>   **for** $j \leftarrow$ *str_start_macro*(e) **to** *str_start_macro*($e + 1$) $- 1$ **do** *append_to_name*(*so*(*str_pool*[j]));
>   **if** $k \leq$ *file_name_size* **then** *name_length* $\leftarrow k$ **else** *name_length* $\leftarrow$ *file_name_size*;
>   **for** $k \leftarrow$ *name_length* $+ 1$ **to** *file_name_size* **do** *name_of_file*[k] $\leftarrow$ ´␣´;
>   **end**;

555. A messier routine is also needed, since format file names must be scanned before T$_{E}$X's string mechanism has been initialized. We shall use the global variable *TEX_format_default* to supply the text for default system areas and extensions related to format files.

> **define** *format_default_length* = 20   {length of the *TEX_format_default* string}
> **define** *format_area_length* = 11   {length of its area part}
> **define** *format_ext_length* = 4   {length of its '.fmt' part}
> **define** *format_extension* = ".fmt"   {the extension, as a WEB constant}

⟨Global variables 13⟩ +≡
TEX_format_default: **packed array** [1 .. *format_default_length*] **of** *char*;

556. ⟨Set initial values of key variables 23⟩ +≡
>   *TEX_format_default* $\leftarrow$ ´TeXformats:plain.fmt´;

557. ⟨Check the "constant" values for consistency 14⟩ +≡
>   **if** *format_default_length* > *file_name_size* **then** *bad* $\leftarrow$ 31;

558.   Here is the messy routine that was just mentioned. It sets *name_of_file* from the first *n* characters of *TEX_format_default*, followed by *buffer*[*a* .. *b*], followed by the last *format_ext_length* characters of *TEX_format_default*.

   We dare not give error messages here, since TEX calls this routine before the *error* routine is ready to roll. Instead, we simply drop excess characters, since the error will be detected in another way when a strange file name isn't found.

procedure *pack_buffered_name*(*n* : *small_number*; *a, b* : *integer*);
  var *k*: *integer*;   { number of positions filled in *name_of_file* }
    c: *ASCII_code*;   { character being packed }
    j: *integer*;   { index into *buffer* or *TEX_format_default* }
  begin if *n* + *b* − *a* + 1 + *format_ext_length* > *file_name_size* **then**
    b ← *a* + *file_name_size* − *n* − 1 − *format_ext_length*;
  k ← 0;
  for *j* ← 1 **to** *n* **do** *append_to_name*(*xord*[*TEX_format_default*[*j*]]);
  for *j* ← *a* **to** *b* **do** *append_to_name*(*buffer*[*j*]);
  for *j* ← *format_default_length* − *format_ext_length* + 1 **to** *format_default_length* **do**
    append_to_name(*xord*[*TEX_format_default*[*j*]]);
  if *k* ≤ *file_name_size* **then** *name_length* ← *k* **else** *name_length* ← *file_name_size*;
  for *k* ← *name_length* + 1 **to** *file_name_size* **do** *name_of_file*[*k*] ← ´␣´;
  end;

559.   Here is the only place we use *pack_buffered_name*. This part of the program becomes active when a "virgin" TEX is trying to get going, just after the preliminary initialization, or when the user is substituting another format file by typing '&' after the initial '**' prompt. The buffer contains the first line of input in *buffer*[*loc* .. (*last* − 1)], where *loc* < *last* and *buffer*[*loc*] ≠ "␣".

⟨ Declare the function called *open_fmt_file* 559 ⟩ ≡
function *open_fmt_file*: *boolean*;
  label *found*, *exit*;
  var *j*: 0 .. *buf_size*;   { the first space after the format file name }
  begin *j* ← *loc*;
  if *buffer*[*loc*] = "&" **then**
    begin *incr*(*loc*); *j* ← *loc*; *buffer*[*last*] ← "␣";
    while *buffer*[*j*] ≠ "␣" **do** *incr*(*j*);
    pack_buffered_name(0, *loc*, *j* − 1);   { try first without the system file area }
    if *w_open_in*(*fmt_file*) **then goto** *found*;
    pack_buffered_name(*format_area_length*, *loc*, *j* − 1);   { now try the system format file area }
    if *w_open_in*(*fmt_file*) **then goto** *found*;
    wake_up_terminal; *wterm_ln*(´Sorry,␣I␣can´´t␣find␣that␣format;´, ´␣will␣try␣PLAIN.´);
    update_terminal;
    end;   { now pull out all the stops: try for the system **plain** file }
  pack_buffered_name(*format_default_length* − *format_ext_length*, 1, 0);
  if ¬*w_open_in*(*fmt_file*) **then**
    begin *wake_up_terminal*; *wterm_ln*(´I␣can´´t␣find␣the␣PLAIN␣format␣file!´);
    open_fmt_file ← *false*; **return**;
    end;
found: *loc* ← *j*; *open_fmt_file* ← *true*;
exit: **end**;

This code is used in section 1357.

560. Operating systems often make it possible to determine the exact name (and possible version number) of a file that has been opened. The following routine, which simply makes a TEX string from the value of *name_of_file*, should ideally be changed to deduce the full name of file f, which is the file most recently opened, if it is possible to do this in a Pascal program.

This routine might be called after string memory has overflowed, hence we dare not use '*str_room*'.

function *make_name_string*: *str_number*;
  var *k*: 0 . . *file_name_size*;   { index into *name_of_file* }
  begin if (*pool_ptr* + *name_length* > *pool_size*) ∨ (*str_ptr* = *max_strings*) ∨ (*cur_length* > 0) **then**
    make_name_string ← "?"
  else begin *make_utf16_name*;
    for *k* ← 0 **to** *name_length16* − 1 **do** *append_char*(*name_of_file16*[*k*]);
    make_name_string ← *make_string*;
    end;
  end;
function *u_make_name_string*(**var** *f* : *unicode_file*): *str_number*;
  begin *u_make_name_string* ← *make_name_string*;
  end;
function *a_make_name_string*(**var** *f* : *alpha_file*): *str_number*;
  begin *a_make_name_string* ← *make_name_string*;
  end;
function *b_make_name_string*(**var** *f* : *byte_file*): *str_number*;
  begin *b_make_name_string* ← *make_name_string*;
  end;
function *w_make_name_string*(**var** *f* : *word_file*): *str_number*;
  begin *w_make_name_string* ← *make_name_string*;
  end;

561. Now let's consider the "driver" routines by which TEX deals with file names in a system-independent manner. First comes a procedure that looks for a file name in the input by calling *get_x_token* for the information.

procedure *scan_file_name*;
  label *done*;
  begin *name_in_progress* ← *true*; *begin_name*; ⟨ Get the next non-blank non-call token 440 ⟩;
  loop begin if (*cur_cmd* > *other_char*) ∨ (*cur_chr* > *biggest_usv*) **then**   { not a character }
    begin *back_input*; **goto** *done*;
    end;
  if ¬*more_name*(*cur_chr*) **then goto** *done*;
  get_x_token;
  end;
done: *end_name*; *name_in_progress* ← *false*;
  end;

562. The global variable *name_in_progress* is used to prevent recursive use of *scan_file_name*, since the *begin_name* and other procedures communicate via global variables. Recursion would arise only by devious tricks like '\input\input f'; such attempts at sabotage must be thwarted. Furthermore, *name_in_progress* prevents \input from being initiated when a font size specification is being scanned.

Another global variable, *job_name*, contains the file name that was first \input by the user. This name is extended by '.log' and '.dvi' and '.fmt' in the names of TEX's output files.

⟨ Global variables 13 ⟩ +≡
name_in_progress: *boolean*;   { is a file name being scanned? }
job_name: *str_number*;   { principal file name }
log_opened: *boolean*;   { has the transcript file been opened? }

563. Initially *job_name* = 0; it becomes nonzero as soon as the true name is known. We have *job_name* = 0 if and only if the 'log' file has not been opened, except of course for a short time just after *job_name* has become nonzero.

⟨ Initialize the output routines 55 ⟩ +≡
  job_name ← 0; *name_in_progress* ← *false*; *log_opened* ← *false*;

564. Here is a routine that manufactures the output file names, assuming that *job_name* ≠ 0. It ignores and changes the current settings of *cur_area* and *cur_ext*.

  define *pack_cur_name* ≡ *pack_file_name*(*cur_name*, *cur_area*, *cur_ext*)

procedure *pack_job_name*(*s* : *str_number*);   { *s* = ".log", *output_file_extension*, or *format_extension* }
  begin *cur_area* ← ""; *cur_ext* ← *s*; *cur_name* ← *job_name*; *pack_cur_name*;
  end;

565. If some trouble arises when TEX tries to open a file, the following routine calls upon the user to supply another file name. Parameter *s* is used in the error message to identify the type of file; parameter *e* is the default extension if none is given. Upon exit from the routine, variables *cur_name*, *cur_area*, *cur_ext*, and *name_of_file* are ready for another attempt at file opening.

procedure *prompt_file_name*(*s*, *e* : *str_number*);
  label *done*;
  var *k*: 0 .. *buf_size*;   { index into *buffer* }
  begin if *interaction* = *scroll_mode* **then** *wake_up_terminal*;
  if *s* = "input␣file␣name" **then** *print_err*("I␣can´t␣find␣file␣`")
  else *print_err*("I␣can´t␣write␣on␣file␣`");
  print_file_name(*cur_name*, *cur_area*, *cur_ext*); *print*("´.");
  if *e* = ".tex" **then** *show_context*;
  print_nl("Please␣type␣another␣"); *print*(*s*);
  if *interaction* < *scroll_mode* **then** *fatal_error*("***␣(job␣aborted,␣file␣error␣in␣nonstop␣mode)");
  clear_terminal; *prompt_input*(":␣"); ⟨ Scan file name in the buffer 566 ⟩;
  if *cur_ext* = "" **then** *cur_ext* ← *e*;
  pack_cur_name;
  end;

566. ⟨Scan file name in the buffer 566⟩ ≡
  begin *begin_name*; *k* ← *first*;
  while (*buffer*[*k*] = "␣") ∧ (*k* < *last*) **do** *incr*(*k*);
  loop begin if *k* = *last* **then goto** *done*;
    if ¬*more_name*(*buffer*[*k*]) **then goto** *done*;
    incr(*k*);
    end;
done: *end_name*;
  end

This code is used in section 565.

567. Here's an example of how these conventions are used. Whenever it is time to ship out a box of stuff, we shall use the macro *ensure_dvi_open*.

  define *ensure_dvi_open* ≡
        if *output_file_name* = 0 **then**
          begin if *job_name* = 0 **then** *open_log_file*;
          pack_job_name(*output_file_extension*);
          while ¬*dvi_open_out*(*dvi_file*) **do**
            prompt_file_name("file␣name␣for␣output", *output_file_extension*);
          output_file_name ← *b_make_name_string*(*dvi_file*);
          end

⟨Global variables 13⟩ +≡
output_file_extension: *str_number*;
no_pdf_output: *boolean*;
dvi_file: *byte_file*; { the device-independent output goes here }
output_file_name: *str_number*; { full name of the output file }
log_name: *str_number*; { full name of the log file }

568. ⟨Initialize the output routines 55⟩ +≡
  output_file_name ← 0;
  if *no_pdf_output* **then** *output_file_extension* ← ".xdv"
  else *output_file_extension* ← ".pdf";

569. The *open_log_file* routine is used to open the transcript file and to help it catch up to what has previously been printed on the terminal.

procedure *open_log_file*;
  var *old_setting*: $0 \mathrel{..} max\_selector$;   { previous *selector* setting }
    k: $0 \mathrel{..} buf\_size$;   { index into *months* and *buffer* }
    l: $0 \mathrel{..} buf\_size$;   { end of first input line }
    months: **packed array** $[1 \mathrel{..} 36]$ **of** *char*;   { abbreviations of month names }
  begin *old_setting* ← *selector*;
  if *job_name* = 0 **then** *job_name* ← "texput";
  pack_job_name(".log");
  while ¬*a_open_out*(*log_file*) **do** ⟨ Try to get a different log file name 570 ⟩;
  log_name ← *a_make_name_string*(*log_file*); *selector* ← *log_only*; *log_opened* ← *true*;
  ⟨ Print the banner line, including the date and time 571 ⟩;
  input_stack[*input_ptr*] ← *cur_input*;   { make sure bottom level is in memory }
  print_nl("**"); *l* ← *input_stack*[0].*limit_field*;   { last position of first line }
  if *buffer*[*l*] = *end_line_char* **then** *decr*(*l*);
  for *k* ← 1 **to** *l* **do** *print*(*buffer*[*k*]);
  print_ln;   { now the transcript file contains the first line of input }
  selector ← *old_setting* + 2;   { *log_only* or *term_and_log* }
  end;

570. Sometimes *open_log_file* is called at awkward moments when T$_{E}$X is unable to print error messages or even to *show_context*. The *prompt_file_name* routine can result in a *fatal_error*, but the *error* routine will not be invoked because *log_opened* will be false.

The normal idea of *batch_mode* is that nothing at all should be written on the terminal. However, in the unusual case that no log file could be opened, we make an exception and allow an explanatory message to be seen.

Incidentally, the program always refers to the log file as a '`transcript file`', because some systems cannot use the extension '`.log`' for this file.

⟨ Try to get a different log file name 570 ⟩ ≡
  begin *selector* ← *term_only*; *prompt_file_name*("transcript␣file␣name", ".log");
  end

This code is used in section 569.

571. ⟨ Print the banner line, including the date and time 571 ⟩ ≡
  begin *wlog*(*banner*); *slow_print*(*format_ident*); *print*("␣␣"); *print_int*(*sys_day*); *print_char*("␣");
  months ← ´JANFEBMARAPRMAYJUNJULAUGSEPOCTNOVDEC´;
  for *k* ← 3 * *sys_month* − 2 **to** 3 * *sys_month* **do** *wlog*(*months*[*k*]);
  print_char("␣"); *print_int*(*sys_year*); *print_char*("␣"); *print_two*(*sys_time* **div** 60); *print_char*(":");
  print_two(*sys_time* **mod** 60);
  if *eTeX_ex* **then**
    begin ; *wlog_cr*; *wlog*(´entering␣extended␣mode´);
    end;
  end

This code is used in section 569.

572. Let's turn now to the procedure that is used to initiate file reading when an '\input' command is being processed. Beware: For historic reasons, this code foolishly conserves a tiny bit of string pool space; but that can confuse the interactive 'E' option.

procedure *start_input*;   { TEX will \input something }
  label *done*;
  begin *scan_file_name*;   { set *cur_name* to desired file name }
  if *cur_ext* = "" **then** *cur_ext* ← ".tex";
  pack_cur_name;
  loop begin *begin_file_reading*;   { set up *cur_file* and new level of input }
    if *a_open_in*(*cur_file*) **then goto** *done*;
    if *cur_area* = "" **then**
      begin *pack_file_name*(*cur_name*, *TEX_area*, *cur_ext*);
      if *a_open_in*(*cur_file*) **then goto** *done*;
      end;
    end_file_reading;   { remove the level that didn't work }
    prompt_file_name("input␣file␣name", ".tex");
    end;
done: *name* ← *a_make_name_string*(*cur_file*);
  if *job_name* = 0 **then**
    begin *job_name* ← *cur_name*; *open_log_file*;
    end;   { *open_log_file* doesn't *show_context*, so *limit* and *loc* needn't be set to meaningful values yet }
  if *term_offset* + *length*(*name*) > *max_print_line* − 2 **then** *print_ln*
  else if (*term_offset* > 0) ∨ (*file_offset* > 0) **then** *print_char*("␣");
  print_char("("); *incr*(*open_parens*); *slow_print*(*name*); *update_terminal*; *state* ← *new_line*;
  if *name* = *str_ptr* − 1 **then**   { conserve string pool space (but see note above) }
    begin *flush_string*; *name* ← *cur_name*;
    end;
  ⟨ Read the first line of the new file 573 ⟩;
  end;

573. Here we have to remember to tell the *input_ln* routine not to start with a *get*. If the file is empty, it is considered to contain a single blank line.

⟨ Read the first line of the new file 573 ⟩ ≡
  begin *line* ← 1;
  if *input_ln*(*cur_file*, *false*) **then** *do_nothing*;
  firm_up_the_line;
  if *end_line_char_inactive* **then** *decr*(*limit*)
  else *buffer*[*limit*] ← *end_line_char*;
  first ← *limit* + 1; *loc* ← *start*;
  end

This code is used in section 572.

574.   Font metric data.   T_EX gets its knowledge about fonts from font metric files, also called `TFM` files; the 'T' in '`TFM`' stands for T_EX, but other programs know about them too.

The information in a `TFM` file appears in a sequence of 8-bit bytes. Since the number of bytes is always a multiple of 4, we could also regard the file as a sequence of 32-bit words, but T_EX uses the byte interpretation. The format of `TFM` files was designed by Lyle Ramshaw in 1980. The intent is to convey a lot of different kinds of information in a compact but useful form.

⟨ Global variables 13 ⟩ +≡
tfm_file: *byte_file*;

575.   The first 24 bytes (6 words) of a `TFM` file contain twelve 16-bit integers that give the lengths of the various subsequent portions of the file. These twelve integers are, in order:

$$lf = \text{length of the entire file, in words;}$$
$$lh = \text{length of the header data, in words;}$$
$$bc = \text{smallest character code in the font;}$$
$$ec = \text{largest character code in the font;}$$
$$nw = \text{number of words in the width table;}$$
$$nh = \text{number of words in the height table;}$$
$$nd = \text{number of words in the depth table;}$$
$$ni = \text{number of words in the italic correction table;}$$
$$nl = \text{number of words in the lig/kern table;}$$
$$nk = \text{number of words in the kern table;}$$
$$ne = \text{number of words in the extensible character table;}$$
$$np = \text{number of font parameter words.}$$

They are all nonnegative and less than 2^{15}. We must have $bc - 1 \le ec \le 255$, and

$$lf = 6 + lh + (ec - bc + 1) + nw + nh + nd + ni + nl + nk + ne + np.$$

Note that a font may contain as many as 256 characters (if $bc = 0$ and $ec = 255$), and as few as 0 characters (if $bc = ec + 1$).

Incidentally, when two or more 8-bit bytes are combined to form an integer of 16 or more bits, the most significant bytes appear first in the file. This is called BigEndian order.

576.   The rest of the `TFM` file may be regarded as a sequence of ten data arrays having the informal specification

$$header : \textbf{array} \ [0 \ .. \ lh - 1] \ \textbf{of} \ stuff$$
$$char\_info : \textbf{array} \ [bc \ .. \ ec] \ \textbf{of} \ char\_info\_word$$
$$width : \textbf{array} \ [0 \ .. \ nw - 1] \ \textbf{of} \ fix\_word$$
$$height : \textbf{array} \ [0 \ .. \ nh - 1] \ \textbf{of} \ fix\_word$$
$$depth : \textbf{array} \ [0 \ .. \ nd - 1] \ \textbf{of} \ fix\_word$$
$$italic : \textbf{array} \ [0 \ .. \ ni - 1] \ \textbf{of} \ fix\_word$$
$$lig\_kern : \textbf{array} \ [0 \ .. \ nl - 1] \ \textbf{of} \ lig\_kern\_command$$
$$kern : \textbf{array} \ [0 \ .. \ nk - 1] \ \textbf{of} \ fix\_word$$
$$exten : \textbf{array} \ [0 \ .. \ ne - 1] \ \textbf{of} \ extensible\_recipe$$
$$param : \textbf{array} \ [1 \ .. \ np] \ \textbf{of} \ fix\_word$$

The most important data type used here is a *fix_word*, which is a 32-bit representation of a binary fraction. A *fix_word* is a signed quantity, with the two's complement of the entire word used to represent negation. Of the 32 bits in a *fix_word*, exactly 12 are to the left of the binary point; thus, the largest *fix_word* value is $2048 - 2^{-20}$, and the smallest is -2048. We will see below, however, that all but two of the *fix_word* values must lie between -16 and $+16$.

577.   The first data array is a block of header information, which contains general facts about the font. The header must contain at least two words, *header*[0] and *header*[1], whose meaning is explained below. Additional header information of use to other software routines might also be included, but TEX82 does not need to know about such details. For example, 16 more words of header information are in use at the Xerox Palo Alto Research Center; the first ten specify the character coding scheme used (e.g., 'XEROX text' or 'TeX math symbols'), the next five give the font identifier (e.g., 'HELVETICA' or 'CMSY'), and the last gives the "face byte." The program that converts DVI files to Xerox printing format gets this information by looking at the TFM file, which it needs to read anyway because of other information that is not explicitly repeated in DVI format.

header[0] is a 32-bit check sum that TEX will copy into the DVI output file. Later on when the DVI file is printed, possibly on another computer, the actual font that gets used is supposed to have a check sum that agrees with the one in the TFM file used by TEX. In this way, users will be warned about potential incompatibilities. (However, if the check sum is zero in either the font file or the TFM file, no check is made.) The actual relation between this check sum and the rest of the TFM file is not important; the check sum is simply an identification number with the property that incompatible fonts almost always have distinct check sums.

header[1] is a *fix_word* containing the design size of the font, in units of TEX points. This number must be at least 1.0; it is fairly arbitrary, but usually the design size is 10.0 for a "10 point" font, i.e., a font that was designed to look best at a 10-point size, whatever that really means. When a TEX user asks for a font 'at δ pt', the effect is to override the design size and replace it by δ, and to multiply the x and y coordinates of the points in the font image by a factor of δ divided by the design size. *All other dimensions in the* TFM *file are fix_word numbers in design-size units*, with the exception of *param*[1] (which denotes the slant ratio). Thus, for example, the value of *param*[6], which defines the em unit, is often the *fix_word* value $2^{20} = 1.0$, since many fonts have a design size equal to one em. The other dimensions must be less than 16 design-size units in absolute value; thus, *header*[1] and *param*[1] are the only *fix_word* entries in the whole TFM file whose first byte might be something besides 0 or 255.

578.   Next comes the *char_info* array, which contains one *char_info_word* per character. Each word in this part of the file contains six fields packed into four bytes as follows.

first byte: *width_index* (8 bits)
second byte: *height_index* (4 bits) times 16, plus *depth_index* (4 bits)
third byte: *italic_index* (6 bits) times 4, plus *tag* (2 bits)
fourth byte: *remainder* (8 bits)

The actual width of a character is *width*[*width_index*], in design-size units; this is a device for compressing information, since many characters have the same width. Since it is quite common for many characters to have the same height, depth, or italic correction, the TFM format imposes a limit of 16 different heights, 16 different depths, and 64 different italic corrections.

The italic correction of a character has two different uses. (a) In ordinary text, the italic correction is added to the width only if the TEX user specifies '\/' after the character. (b) In math formulas, the italic correction is always added to the width, except with respect to the positioning of subscripts.

Incidentally, the relation *width*[0] = *height*[0] = *depth*[0] = *italic*[0] = 0 should always hold, so that an index of zero implies a value of zero. The *width_index* should never be zero unless the character does not exist in the font, since a character is valid if and only if it lies between *bc* and *ec* and has a nonzero *width_index*.

579.   The *tag* field in a *char_info_word* has four values that explain how to interpret the *remainder* field.

$tag = 0$ (*no_tag*) means that *remainder* is unused.

$tag = 1$ (*lig_tag*) means that this character has a ligature/kerning program starting at position *remainder* in the *lig_kern* array.

$tag = 2$ (*list_tag*) means that this character is part of a chain of characters of ascending sizes, and not the largest in the chain. The *remainder* field gives the character code of the next larger character.

$tag = 3$ (*ext_tag*) means that this character code represents an extensible character, i.e., a character that is built up of smaller pieces so that it can be made arbitrarily large. The pieces are specified in *exten*[*remainder*].

Characters with $tag = 2$ and $tag = 3$ are treated as characters with $tag = 0$ unless they are used in special circumstances in math formulas. For example, the \sum operation looks for a *list_tag*, and the \left operation looks for both *list_tag* and *ext_tag*.

  define *no_tag* $= 0$ { vanilla character }
  define *lig_tag* $= 1$ { character has a ligature/kerning program }
  define *list_tag* $= 2$ { character has a successor in a charlist }
  define *ext_tag* $= 3$ { character is extensible }

580.   The *lig_kern* array contains instructions in a simple programming language that explains what to do for special letter pairs. Each word in this array is a *lig_kern_command* of four bytes.

first byte: *skip_byte*, indicates that this is the final program step if the byte is 128 or more, otherwise the next step is obtained by skipping this number of intervening steps.

second byte: *next_char*, "if *next_char* follows the current character, then perform the operation and stop, otherwise continue."

third byte: *op_byte*, indicates a ligature step if less than 128, a kern step otherwise.

fourth byte: *remainder*.

In a kern step, an additional space equal to $kern[256*(op\_byte-128)+remainder]$ is inserted between the current character and *next_char*. This amount is often negative, so that the characters are brought closer together by kerning; but it might be positive.

There are eight kinds of ligature steps, having *op_byte* codes $4a+2b+c$ where $0 \le a \le b+c$ and $0 \le b, c \le 1$. The character whose code is *remainder* is inserted between the current character and *next_char*; then the current character is deleted if $b = 0$, and *next_char* is deleted if $c = 0$; then we pass over a characters to reach the next current character (which may have a ligature/kerning program of its own).

If the very first instruction of the *lig_kern* array has *skip_byte* = 255, the *next_char* byte is the so-called boundary character of this font; the value of *next_char* need not lie between *bc* and *ec*. If the very last instruction of the *lig_kern* array has *skip_byte* = 255, there is a special ligature/kerning program for a boundary character at the left, beginning at location $256 * op\_byte + remainder$. The interpretation is that TEX puts implicit boundary characters before and after each consecutive string of characters from the same font. These implicit characters do not appear in the output, but they can affect ligatures and kerning.

If the very first instruction of a character's *lig_kern* program has *skip_byte* > 128, the program actually begins in location $256 * op\_byte + remainder$. This feature allows access to large *lig_kern* arrays, because the first instruction must otherwise appear in a location ≤ 255.

Any instruction with *skip_byte* > 128 in the *lig_kern* array must satisfy the condition

$$256 * op\_byte + remainder < nl.$$

If such an instruction is encountered during normal program execution, it denotes an unconditional halt; no ligature or kerning command is performed.

   define *stop_flag* $\equiv qi(128)$ { value indicating 'STOP' in a lig/kern program }
   define *kern_flag* $\equiv qi(128)$ { op code for a kern step }
   define *skip_byte*(#) $\equiv$ #.*b0*
   define *next_char*(#) $\equiv$ #.*b1*
   define *op_byte*(#) $\equiv$ #.*b2*
   define *rem_byte*(#) $\equiv$ #.*b3*

581.   Extensible characters are specified by an *extensible_recipe*, which consists of four bytes called *top*, *mid*, *bot*, and *rep* (in this order). These bytes are the character codes of individual pieces used to build up a large symbol. If *top*, *mid*, or *bot* are zero, they are not present in the built-up result. For example, an extensible vertical line is like an extensible bracket, except that the top and bottom pieces are missing.

Let T, M, B, and R denote the respective pieces, or an empty box if the piece isn't present. Then the extensible characters have the form TR^kMR^kB from top to bottom, for some $k \ge 0$, unless M is absent; in the latter case we can have TR^kB for both even and odd values of k. The width of the extensible character is the width of R; and the height-plus-depth is the sum of the individual height-plus-depths of the components used, since the pieces are butted together in a vertical list.

   define *ext_top*(#) $\equiv$ #.*b0*   { *top* piece in a recipe }
   define *ext_mid*(#) $\equiv$ #.*b1*   { *mid* piece in a recipe }
   define *ext_bot*(#) $\equiv$ #.*b2*   { *bot* piece in a recipe }
   define *ext_rep*(#) $\equiv$ #.*b3*   { *rep* piece in a recipe }

582.   The final portion of a TFM file is the *param* array, which is another sequence of *fix_word* values.

param[1] = *slant* is the amount of italic slant, which is used to help position accents. For example, *slant* = .25 means that when you go up one unit, you also go .25 units to the right. The *slant* is a pure number; it's the only *fix_word* other than the design size itself that is not scaled by the design size.

param[2] = *space* is the normal spacing between words in text. Note that character "␣" in the font need not have anything to do with blank spaces.

param[3] = *space_stretch* is the amount of glue stretching between words.

param[4] = *space_shrink* is the amount of glue shrinking between words.

param[5] = *x_height* is the size of one ex in the font; it is also the height of letters for which accents don't have to be raised or lowered.

param[6] = *quad* is the size of one em in the font.

param[7] = *extra_space* is the amount added to *param*[2] at the ends of sentences.

If fewer than seven parameters are present, TEX sets the missing parameters to zero. Fonts used for math symbols are required to have additional parameter information, which is explained later.

> **define** *slant_code* = 1
> **define** *space_code* = 2
> **define** *space_stretch_code* = 3
> **define** *space_shrink_code* = 4
> **define** *x_height_code* = 5
> **define** *quad_code* = 6
> **define** *extra_space_code* = 7

583.   So that is what TFM files hold. Since TEX has to absorb such information about lots of fonts, it stores most of the data in a large array called *font_info*. Each item of *font_info* is a *memory_word*; the *fix_word* data gets converted into *scaled* entries, while everything else goes into words of type *four_quarters*.

When the user defines \font\f, say, TEX assigns an internal number to the user's font \f. Adding this number to *font_id_base* gives the *eqtb* location of a "frozen" control sequence that will always select the font.

⟨ Types in the outer block 18 ⟩ +≡
> *internal_font_number* = *font_base* .. *font_max*;   { *font* in a *char_node* }
> *font_index* = 0 .. *font_mem_size*;   { index into *font_info* }

584.   Here now is the (rather formidable) array of font arrays.

> **define** $otgr\_font\_flag = ″\text{FFFE}$
> **define** $aat\_font\_flag = ″\text{FFFF}$
> **define** $is\_aat\_font(\#) \equiv (font\_area[\#] = aat\_font\_flag)$
> **define** $is\_ot\_font(\#) \equiv ((font\_area[\#] = otgr\_font\_flag) \wedge (usingOpenType(font\_layout\_engine[\#])))$
> **define** $is\_gr\_font(\#) \equiv ((font\_area[\#] = otgr\_font\_flag) \wedge (usingGraphite(font\_layout\_engine[\#])))$
> **define** $is\_otgr\_font(\#) \equiv (font\_area[\#] = otgr\_font\_flag)$
> **define** $is\_native\_font(\#) \equiv (is\_aat\_font(\#) \vee is\_otgr\_font(\#))$ { native fonts have $font\_area = 65534$ or 65535, which would be a string containing an invalid Unicode character }
> **define**
> $$is\_new\_mathfont(\#) \equiv ((font\_area[\#] = otgr\_font\_flag) \wedge (isOpenTypeMathFont(font\_layout\_engine[\#])))$$
> **define** $non\_char \equiv qi(too\_big\_char)$ { a *halfword* code that can't match a real character }
> **define** $non\_address = 0$ { a spurious *bchar_label* }

⟨Global variables 13⟩ +≡
font_info: **array** [*font_index*] **of** *memory_word*;   { the big collection of font data }
fmem_ptr: *font_index*;   { first unused word of *font_info* }
font_ptr: *internal_font_number*;   { largest internal font number in use }
font_check: **array** [*internal_font_number*] **of** *four_quarters*;   { check sum }
font_size: **array** [*internal_font_number*] **of** *scaled*;   { "at" size }
font_dsize: **array** [*internal_font_number*] **of** *scaled*;   { "design" size }
font_params: **array** [*internal_font_number*] **of** *font_index*;   { how many font parameters are present }
font_name: **array** [*internal_font_number*] **of** *str_number*;   { name of the font }
font_area: **array** [*internal_font_number*] **of** *str_number*;   { area of the font }
font_bc: **array** [*internal_font_number*] **of** *eight_bits*;   { beginning (smallest) character code }
font_ec: **array** [*internal_font_number*] **of** *eight_bits*;   { ending (largest) character code }
font_glue: **array** [*internal_font_number*] **of** *pointer*;
        { glue specification for interword space, *null* if not allocated }
font_used: **array** [*internal_font_number*] **of** *boolean*;
        { has a character from this font actually appeared in the output? }
hyphen_char: **array** [*internal_font_number*] **of** *integer*;   { current \hyphenchar values }

bchar_label: **array** [*internal_font_number*] **of** *font_index*;
        { start of *lig_kern* program for left boundary character, *non_address* if there is none }
font_bchar: **array** [*internal_font_number*] **of** *min_quarterword* .. *non_char*;
        { boundary character, *non_char* if there is none }
font_false_bchar: **array** [*internal_font_number*] **of** *min_quarterword* .. *non_char*;
        { *font_bchar* if it doesn't exist in the font, otherwise *non_char* }

585. Besides the arrays just enumerated, we have directory arrays that make it easy to get at the individual entries in *font_info*. For example, the *char_info* data for character c in font f will be in *font_info*[*char_base*[f] + c].*qqqq*; and if w is the *width_index* part of this word (the *b0* field), the width of the character is *font_info*[*width_base*[f] + w].*sc*. (These formulas assume that *min_quarterword* has already been added to c and to w, since TEX stores its quarterwords that way.)

⟨ Global variables 13 ⟩ +≡

588. ⟨ Put each of TEX's primitives into the hash table 252 ⟩ +≡

  primitive("nullfont", *set_font*, *null_font*); *text*(*frozen_null_font*) ← "nullfont";

  eqtb[*frozen_null_font*] ← *eqtb*[*cur_val*];

589.   Of course we want to define macros that suppress the detail of how font information is actually packed, so that we don't have to write things like

$$font\_info[width\_base[f] + font\_info[char\_base[f] + c].qqqq.b0].sc$$

too often.   The WEB definitions here make $char\_info(f)(c)$ the $four\_quarters$ word of font information corresponding to character c of font f. If q is such a word, $char\_width(f)(q)$ will be the character's width; hence the long formula above is at least abbreviated to

$$char\_width(f)(char\_info(f)(c)).$$

Usually, of course, we will fetch q first and look at several of its fields at the same time.

The italic correction of a character will be denoted by $char\_italic(f)(q)$, so it is analogous to $char\_width$. But we will get at the height and depth in a slightly different way, since we usually want to compute both height and depth if we want either one. The value of $height\_depth(q)$ will be the 8-bit quantity

$$b = height\_index \times 16 + depth\_index,$$

and if b is such a byte we will write $char\_height(f)(b)$ and $char\_depth(f)(b)$ for the height and depth of the character c for which $q = char\_info(f)(c)$. Got that?

The tag field will be called $char\_tag(q)$; the remainder byte will be called $rem\_byte(q)$, using a macro that we have already defined above.

Access to a character's $width$, $height$, $depth$, and tag fields is part of TEX's inner loop, so we want these macros to produce code that is as fast as possible under the circumstances.

> **define** $char\_info\_end(\#) \equiv \# \;] \; .qqqq$
> **define** $char\_info(\#) \equiv font\_info \; [\; char\_base[\#] + char\_info\_end$
> **define** $char\_width\_end(\#) \equiv \#.b0 \;] \; .sc$
> **define** $char\_width(\#) \equiv font\_info \; [\; width\_base[\#] + char\_width\_end$
> **define** $char\_exists(\#) \equiv (\#.b0 > min\_quarterword)$
> **define** $char\_italic\_end(\#) \equiv (qo(\#.b2)) \; \textbf{div} \; 4 \;] \; .sc$
> **define** $char\_italic(\#) \equiv font\_info \; [\; italic\_base[\#] + char\_italic\_end$
> **define** $height\_depth(\#) \equiv qo(\#.b1)$
> **define** $char\_height\_end(\#) \equiv (\#) \; \textbf{div} \; 16 \;] \; .sc$
> **define** $char\_height(\#) \equiv font\_info \; [\; height\_base[\#] + char\_height\_end$
> **define** $char\_depth\_end(\#) \equiv (\#) \; \textbf{mod} \; 16 \;] \; .sc$
> **define** $char\_depth(\#) \equiv font\_info \; [\; depth\_base[\#] + char\_depth\_end$
> **define** $char\_tag(\#) \equiv ((qo(\#.b2)) \; \textbf{mod} \; 4)$

590.   The global variable $null\_character$ is set up to be a word of $char\_info$ for a character that doesn't exist. Such a word provides a convenient way to deal with erroneous situations.

⟨ Global variables 13 ⟩ +≡
$null\_character$: $four\_quarters$;   { nonexistent character information }

591.   ⟨ Set initial values of key variables 23 ⟩ +≡
$null\_character.b0 \leftarrow min\_quarterword$; $null\_character.b1 \leftarrow min\_quarterword$;
$null\_character.b2 \leftarrow min\_quarterword$; $null\_character.b3 \leftarrow min\_quarterword$;

592.   Here are some macros that help process ligatures and kerns. We write $char\_kern(f)(j)$ to find the amount of kerning specified by kerning command j in font f. If j is the $char\_info$ for a character with a ligature/kern program, the first instruction of that program is either $i = font\_info[lig\_kern\_start(f)(j)]$ or $font\_info[lig\_kern\_restart(f)(i)]$, depending on whether or not $skip\_byte(i) \leq stop\_flag$.

The constant $kern\_base\_offset$ should be simplified, for Pascal compilers that do not do local optimization.

define $char\_kern\_end(\#) \equiv 256 * op\_byte(\#) + rem\_byte(\#) \ ] \ .sc$
define $char\_kern(\#) \equiv font\_info \ [\ kern\_base[\#] + char\_kern\_end$
define $kern\_base\_offset \equiv 256 * (128 + min\_quarterword)$
define $lig\_kern\_start(\#) \equiv lig\_kern\_base[\#] + rem\_byte$ { beginning of lig/kern program }
define $lig\_kern\_restart\_end(\#) \equiv 256 * op\_byte(\#) + rem\_byte(\#) + 32768 - kern\_base\_offset$
define $lig\_kern\_restart(\#) \equiv lig\_kern\_base[\#] + lig\_kern\_restart\_end$

593.   Font parameters are referred to as $slant(f)$, $space(f)$, etc.

define $param\_end(\#) \equiv param\_base[\#] \ ] \ .sc$
define $param(\#) \equiv font\_info \ [\ \# + param\_end$
define $slant \equiv param(slant\_code)$ { slant to the right, per unit distance upward }
define $space \equiv param(space\_code)$ { normal space between words }
define $space\_stretch \equiv param(space\_stretch\_code)$ { stretch between words }

⟨ The em width for cur_font 593 ⟩ ≡
  $quad(cur\_font)$

This code is used in section 490.

594.   ⟨ The x-height for cur_font 594 ⟩ ≡
  $x\_height(cur\_font)$

This code is used in section 490.

595. TEX checks the information of a `TFM` file for validity as the file is being read in, so that no further checks will be needed when typesetting is going on. The somewhat tedious subroutine that does this is called *read_font_info*. It has four parameters: the user font identifier u, the file name and area strings *nom* and *aire*, and the "at" size s. If s is negative, it's the negative of a scale factor to be applied to the design size; $s = -1000$ is the normal case. Otherwise s will be substituted for the design size; in this case, s must be positive and less than 2048 pt (i.e., it must be less than 2^{27} when considered as an integer).

The subroutine opens and closes a global file variable called *tfm_file*. It returns the value of the internal font number that was just loaded. If an error is detected, an error message is issued and no font information is stored; *null_font* is returned in this case.

> **define** *bad_tfm* = 11   { label for *read_font_info* }
> **define** *abort* ≡ **goto** *bad_tfm*   { do this when the `TFM` data is wrong }

    ext_tag: **if** $d \geq ne$ **then** *abort*;
    list_tag: ⟨Check for charlist cycle 605⟩;
    othercases *do_nothing* { *no_tag* }
    endcases;
    end

This code is used in section 597.

605.   We want to make sure that there is no cycle of characters linked together by *list_tag* entries, since such a cycle would get TEX into an endless loop. If such a cycle exists, the routine here detects it when processing the largest character code in the cycle.

  define *check_byte_range*(#) ≡
        begin if $(\# < bc) \vee (\# > ec)$ **then** *abort*
        end
  define *current_character_being_worked_on* ≡ $k + bc -$ *fmem_ptr*

⟨Check for charlist cycle 605⟩ ≡
  begin *check_byte_range*(*d*);
  while $d <$ *current_character_being_worked_on* **do**
    begin $qw \leftarrow$ *char_info*(*f*)(*d*);   { N.B.: not *qi*(*d*), since *char_base*[*f*] hasn't been adjusted yet }
    if *char_tag*(*qw*) ≠ *list_tag* **then goto** *not_found*;
    $d \leftarrow$ *qo*(*rem_byte*(*qw*));   { next character on the list }
    end;
  if $d =$ *current_character_being_worked_on* **then** *abort*;   { yes, there's a cycle }
not_found: **end**

This code is used in section 604.

606.   A *fix_word* whose four bytes are (a, b, c, d) from left to right represents the number

$$x = \begin{cases} b \cdot 2^{-4} + c \cdot 2^{-12} + d \cdot 2^{-20}, & \text{if } a = 0; \\ -16 + b \cdot 2^{-4} + c \cdot 2^{-12} + d \cdot 2^{-20}, & \text{if } a = 255. \end{cases}$$

(No other choices of a are allowed, since the magnitude of a number in design-size units must be less than 16.) We want to multiply this quantity by the integer z, which is known to be less than 2^{27}. If $z < 2^{23}$, the individual multiplications $b \cdot z$, $c \cdot z$, $d \cdot z$ cannot overflow; otherwise we will divide z by 2, 4, 8, or 16, to obtain a multiplier less than 2^{23}, and we can compensate for this later. If z has thereby been replaced by $z' = z/2^e$, let $\beta = 2^{4-e}$; we shall compute

$$\lfloor (b + c \cdot 2^{-8} + d \cdot 2^{-16}) z'/\beta \rfloor$$

if $a = 0$, or the same quantity minus $\alpha = 2^{4+e} z'$ if $a = 255$. This calculation must be done exactly, in order to guarantee portability of TEX between computers.

> **define** *store_scaled*(#) ≡
> > **begin** *fget*; $a \leftarrow$ *fbyte*; *fget*; $b \leftarrow$ *fbyte*; *fget*; $c \leftarrow$ *fbyte*; *fget*; $d \leftarrow$ *fbyte*;

This code is used in section 597.

612. Before we forget about the format of these tables, let's deal with two of TEX's basic scanning routines related to font information.

⟨Declare procedures that scan font-related stuff 612⟩ ≡
procedure $scan\_font\_ident$;
  var f: $internal\_font\_number$; m: $halfword$;
  begin ⟨Get the next non-blank non-call token 440⟩;
  if $cur\_cmd = def\_font$ **then** $f \leftarrow cur\_font$
  else if $cur\_cmd = set\_font$ **then** $f \leftarrow cur\_chr$
    else if $cur\_cmd = def\_family$ **then**
        begin $m \leftarrow cur\_chr$; $scan\_math\_fam\_int$; $f \leftarrow equiv(m + cur\_val)$;
        end
      else begin $print\_err($"Missing␣font␣identifier"$)$;
        $help2($"I␣was␣looking␣for␣a␣control␣sequence␣whose"$)$
        ($"current␣meaning␣has␣been␣defined␣by␣\font."$); $back\_error$; $f \leftarrow null\_font$;
        end;
  $cur\_val \leftarrow f$;
  end;

See also section 613.

This code is used in section 443.

613. The following routine is used to implement '\fontdimen n f'. The boolean parameter *writing* is set *true* if the calling program intends to change the parameter value.

⟨Declare procedures that scan font-related stuff 612⟩ +≡

procedure *find_font_dimen*(*writing* : *boolean*); {sets *cur_val* to *font_info* location}
  var *f*: *internal_font_number*; *n*: *integer*; {the parameter number}
  begin *scan_int*; *n* ← *cur_val*; *scan_font_ident*; *f* ← *cur_val*;
  if $n \le 0$ **then** *cur_val* ← *fmem_ptr*
  else begin if *writing* ∧ ($n \le space\_shrink\_code$) ∧ ($n \ge space\_code$) ∧ (*font_glue*[f] ≠ *null*) **then**
      begin *delete_glue_ref*(*font_glue*[f]); *font_glue*[f] ← *null*;
      end;
    if $n > font\_params[f]$ **then**
      if $f < font\_ptr$ **then** *cur_val* ← *fmem_ptr*
      else ⟨Increase the number of parameters in the last font 615⟩
    else *cur_val* ← $n + param\_base[f]$;
    end;
  ⟨Issue an error message if *cur_val* = *fmem_ptr* 614⟩;
  end;

614. ⟨Issue an error message if *cur_val* = *fmem_ptr* 614⟩ ≡
  if *cur_val* = *fmem_ptr* **then**
    begin *print_err*("Font␣"); *print_esc*(*font_id_text*(f)); *print*("␣has␣only␣");
    print_int(*font_params*[f]); *print*("␣fontdimen␣parameters");
    help2("To␣increase␣the␣number␣of␣font␣parameters,␣you␣must")
    ("use␣\fontdimen␣immediately␣after␣the␣\font␣is␣loaded."); *error*;
    end

This code is used in section 613.

615. ⟨Increase the number of parameters in the last font 615⟩ ≡
  begin repeat if *fmem_ptr* = *font_mem_size* **then** *overflow*("font␣memory", *font_mem_size*);
    font_info[*fmem_ptr*].*sc* ← 0; *incr*(*fmem_ptr*); *incr*(*font_params*[f]);
  until $n = font\_params[f]$;
  cur_val ← *fmem_ptr* − 1; {this equals $param\_base[f] + font\_params[f]$}
  end

This code is used in section 613.

616.   When TEX wants to typeset a character that doesn't exist, the character node is not created; thus the output routine can assume that characters exist when it sees them. The following procedure prints a warning message unless the user has suppressed it.

⟨ Declare subroutines for *new_character* 616 ⟩ ≡
procedure *char_warning*(*f* : *internal_font_number*; *c* : *integer*);
  var *old_setting*: *integer*;   { saved value of *tracing_online* }
  begin if *tracing_lost_chars* > 0 **then**
    begin *old_setting* ← *tracing_online*;
    if *eTeX_ex* ∧ (*tracing_lost_chars* > 1) **then** *tracing_online* ← 1;
    begin *begin_diagnostic*; *print_nl*("Missing␣character:␣There␣is␣no␣");
    if *c* < ″10000 **then** *print_ASCII*(*c*)
    else *print_char*(*c*);   { non-Plane 0 Unicodes can't be sent through *print_ASCII* }
    print("␣in␣font␣"); *slow_print*(*font_name*[*f*]); *print_char*("!"); *end_diagnostic*(*false*);
    end; *tracing_online* ← *old_setting*;
    end;
  end;
See also section 744.
This code is used in section 617.

617.   We need a few subroutines for *new_character*.

⟨ Declare subroutines for *new_character* 616 ⟩

618.   Here is a function that returns a pointer to a character node for a given character in a given font. If that character doesn't exist, *null* is returned instead.

function *new_character*(*f* : *internal_font_number*; *c* : *eight_bits*): *pointer*;
  label *exit*;
  var *p*: *pointer*;   { newly allocated node }
  begin if *font_bc*[*f*] ≤ *c* **then**
    if *font_ec*[*f*] ≥ *c* **then**
      if *char_exists*(*char_info*(*f*)(*qi*(*c*))) **then**
        begin *p* ← *get_avail*; *font*(*p*) ← *f*; *character*(*p*) ← *qi*(*c*); *new_character* ← *p*; **return**;
        end;
  char_warning(*f*, *c*); *new_character* ← *null*;
exit: **end**;

619.   Device-independent file format.   The most important output produced by a run of TEX is the "device independent" (DVI) file that specifies where characters and rules are to appear on printed pages. The form of these files was designed by David R. Fuchs in 1979. Almost any reasonable typesetting device can be driven by a program that takes DVI files as input, and dozens of such DVI-to-whatever programs have been written. Thus, it is possible to print the output of TEX on many different kinds of equipment, using TEX as a device-independent "front end."

A DVI file is a stream of 8-bit bytes, which may be regarded as a series of commands in a machine-like language. The first byte of each command is the operation code, and this code is followed by zero or more bytes that provide parameters to the command. The parameters themselves may consist of several consecutive bytes; for example, the '*set_rule*' command has two parameters, each of which is four bytes long. Parameters are usually regarded as nonnegative integers; but four-byte-long parameters, and shorter parameters that denote distances, can be either positive or negative. Such parameters are given in two's complement notation. For example, a two-byte-long distance parameter has a value between -2^{15} and $2^{15} - 1$. As in TFM files, numbers that occupy more than one byte position appear in BigEndian order.

XTEX extends the format of DVI with its own commands, and thus produced "extended device independent" (XDV) files.

A DVI file consists of a "preamble," followed by a sequence of one or more "pages," followed by a "postamble." The preamble is simply a *pre* command, with its parameters that define the dimensions used in the file; this must come first. Each "page" consists of a *bop* command, followed by any number of other commands that tell where characters are to be placed on a physical page, followed by an *eop* command. The pages appear in the order that TEX generated them. If we ignore *nop* commands and *fnt_def* commands (which are allowed between any two commands in the file), each *eop* command is immediately followed by a *bop* command, or by a *post* command; in the latter case, there are no more pages in the file, and the remaining bytes form the postamble. Further details about the postamble will be explained later.

Some parameters in DVI commands are "pointers." These are four-byte quantities that give the location number of some other byte in the file; the first byte is number 0, then comes number 1, and so on. For example, one of the parameters of a *bop* command points to the previous *bop*; this makes it feasible to read the pages in backwards order, in case the results are being directed to a device that stacks its output face up. Suppose the preamble of a DVI file occupies bytes 0 to 99. Now if the first page occupies bytes 100 to 999, say, and if the second page occupies bytes 1000 to 1999, then the *bop* that starts in byte 1000 points to 100 and the *bop* that starts in byte 2000 points to 1000. (The very first *bop*, i.e., the one starting in byte 100, has a pointer of -1.)

620.   The DVI format is intended to be both compact and easily interpreted by a machine. Compactness is achieved by making most of the information implicit instead of explicit. When a DVI-reading program reads the commands for a page, it keeps track of several quantities: (a) The current font f is an integer; this value is changed only by *fnt* and *fnt_num* commands. (b) The current position on the page is given by two numbers called the horizontal and vertical coordinates, h and v. Both coordinates are zero at the upper left corner of the page; moving to the right corresponds to increasing the horizontal coordinate, and moving down corresponds to increasing the vertical coordinate. Thus, the coordinates are essentially Cartesian, except that vertical directions are flipped; the Cartesian version of (h, v) would be $(h, -v)$. (c) The current spacing amounts are given by four numbers w, x, y, and z, where w and x are used for horizontal spacing and where y and z are used for vertical spacing. (d) There is a stack containing (h, v, w, x, y, z) values; the DVI commands *push* and *pop* are used to change the current level of operation. Note that the current font f is not pushed and popped; the stack contains only information about positioning.

The values of h, v, w, x, y, and z are signed integers having up to 32 bits, including the sign. Since they represent physical distances, there is a small unit of measurement such that increasing h by 1 means moving a certain tiny distance to the right. The actual unit of measurement is variable, as explained below; TEX sets things up so that its DVI output is in sp units, i.e., scaled points, in agreement with all the *scaled* dimensions in TEX's data structures.

621. Here is a list of all the commands that may appear in a XDV file. Each command is specified by its symbolic name (e.g., *bop*), its opcode byte (e.g., 139), and its parameters (if any). The parameters are followed by a bracketed number telling how many bytes they occupy; for example, '$p[4]$' means that parameter p is four bytes long.

set_char_0 0. Typeset character number 0 from font f such that the reference point of the character is at (h, v). Then increase h by the width of that character. Note that a character may have zero or negative width, so one cannot be sure that h will advance after this command; but h usually does increase.

set_char_1 through *set_char_127* (opcodes 1 to 127). Do the operations of *set_char_0*; but use the character whose number matches the opcode, instead of character 0.

set1 128 $c[1]$. Same as *set_char_0*, except that character number c is typeset. TEX82 uses this command for characters in the range $128 \le c < 256$.

set2 129 $c[2]$. Same as *set1*, except that c is two bytes long, so it is in the range $0 \le c < 65536$. TEX82 never uses this command, but it should come in handy for extensions of TEX that deal with oriental languages.

set3 130 $c[3]$. Same as *set1*, except that c is three bytes long, so it can be as large as $2^{24} - 1$. Not even the Chinese language has this many characters, but this command might prove useful in some yet unforeseen extension.

set4 131 $c[4]$. Same as *set1*, except that c is four bytes long. Imagine that.

set_rule 132 $a[4]$ $b[4]$. Typeset a solid black rectangle of height a and width b, with its bottom left corner at (h, v). Then set $h \leftarrow h + b$. If either $a \le 0$ or $b \le 0$, nothing should be typeset. Note that if $b < 0$, the value of h will decrease even though nothing else happens. See below for details about how to typeset rules so that consistency with METAFONT is guaranteed.

put1 133 $c[1]$. Typeset character number c from font f such that the reference point of the character is at (h, v). (The 'put' commands are exactly like the 'set' commands, except that they simply put out a character or a rule without moving the reference point afterwards.)

put2 134 $c[2]$. Same as *set2*, except that h is not changed.

put3 135 $c[3]$. Same as *set3*, except that h is not changed.

put4 136 $c[4]$. Same as *set4*, except that h is not changed.

put_rule 137 $a[4]$ $b[4]$. Same as *set_rule*, except that h is not changed.

nop 138. No operation, do nothing. Any number of *nop*'s may occur between DVI commands, but a *nop* cannot be inserted between a command and its parameters or between two parameters.

bop 139 $c_0[4]$ $c_1[4]$ ... $c_9[4]$ $p[4]$. Beginning of a page: Set $(h, v, w, x, y, z) \leftarrow (0, 0, 0, 0, 0, 0)$ and set the stack empty. Set the current font f to an undefined value. The ten c_i parameters hold the values of \count0 ... \count9 in TEX at the time \shipout was invoked for this page; they can be used to identify pages, if a user wants to print only part of a DVI file. The parameter p points to the previous *bop* in the file; the first *bop* has $p = -1$.

eop 140. End of page: Print what you have read since the previous *bop*. At this point the stack should be empty. (The DVI-reading programs that drive most output devices will have kept a buffer of the material that appears on the page that has just ended. This material is largely, but not entirely, in order by v coordinate and (for fixed v) by h coordinate; so it usually needs to be sorted into some order that is appropriate for the device in question.)

push 141. Push the current values of (h, v, w, x, y, z) onto the top of the stack; do not change any of these values. Note that f is not pushed.

pop 142. Pop the top six values off of the stack and assign them respectively to (h, v, w, x, y, z). The number of pops should never exceed the number of pushes, since it would be highly embarrassing if the stack were empty at the time of a *pop* command.

right1 143 $b[1]$. Set $h \leftarrow h + b$, i.e., move right b units. The parameter is a signed number in two's complement notation, $-128 \le b < 128$; if $b < 0$, the reference point moves left.

right2 144 $b[2]$. Same as *right1*, except that b is a two-byte quantity in the range $-32768 \le b < 32768$.

right3 145 $b[3]$. Same as *right1*, except that b is a three-byte quantity in the range $-2^{23} \le b < 2^{23}$.

right4 146 $b[4]$. Same as *right1*, except that b is a four-byte quantity in the range $-2^{31} \le b < 2^{31}$.

w0 147. Set $h \leftarrow h + w$; i.e., move right w units. With luck, this parameterless command will usually suffice, because the same kind of motion will occur several times in succession; the following commands explain how w gets particular values.

w1 148 $b[1]$. Set $w \leftarrow b$ and $h \leftarrow h + b$. The value of b is a signed quantity in two's complement notation, $-128 \le b < 128$. This command changes the current w spacing and moves right by b.

w2 149 $b[2]$. Same as *w1*, but b is two bytes long, $-32768 \le b < 32768$.

w3 150 $b[3]$. Same as *w1*, but b is three bytes long, $-2^{23} \le b < 2^{23}$.

w4 151 $b[4]$. Same as *w1*, but b is four bytes long, $-2^{31} \le b < 2^{31}$.

x0 152. Set $h \leftarrow h + x$; i.e., move right x units. The 'x' commands are like the 'w' commands except that they involve x instead of w.

x1 153 $b[1]$. Set $x \leftarrow b$ and $h \leftarrow h + b$. The value of b is a signed quantity in two's complement notation, $-128 \le b < 128$. This command changes the current x spacing and moves right by b.

x2 154 $b[2]$. Same as *x1*, but b is two bytes long, $-32768 \le b < 32768$.

x3 155 $b[3]$. Same as *x1*, but b is three bytes long, $-2^{23} \le b < 2^{23}$.

x4 156 $b[4]$. Same as *x1*, but b is four bytes long, $-2^{31} \le b < 2^{31}$.

down1 157 $a[1]$. Set $v \leftarrow v + a$, i.e., move down a units. The parameter is a signed number in two's complement notation, $-128 \le a < 128$; if $a < 0$, the reference point moves up.

down2 158 $a[2]$. Same as *down1*, except that a is a two-byte quantity in the range $-32768 \le a < 32768$.

down3 159 $a[3]$. Same as *down1*, except that a is a three-byte quantity in the range $-2^{23} \le a < 2^{23}$.

down4 160 $a[4]$. Same as *down1*, except that a is a four-byte quantity in the range $-2^{31} \le a < 2^{31}$.

y0 161. Set $v \leftarrow v + y$; i.e., move down y units. With luck, this parameterless command will usually suffice, because the same kind of motion will occur several times in succession; the following commands explain how y gets particular values.

y1 162 $a[1]$. Set $y \leftarrow a$ and $v \leftarrow v + a$. The value of a is a signed quantity in two's complement notation, $-128 \le a < 128$. This command changes the current y spacing and moves down by a.

y2 163 $a[2]$. Same as *y1*, but a is two bytes long, $-32768 \le a < 32768$.

y3 164 $a[3]$. Same as *y1*, but a is three bytes long, $-2^{23} \le a < 2^{23}$.

y4 165 $a[4]$. Same as *y1*, but a is four bytes long, $-2^{31} \le a < 2^{31}$.

z0 166. Set $v \leftarrow v + z$; i.e., move down z units. The 'z' commands are like the 'y' commands except that they involve z instead of y.

z1 167 $a[1]$. Set $z \leftarrow a$ and $v \leftarrow v + a$. The value of a is a signed quantity in two's complement notation, $-128 \le a < 128$. This command changes the current z spacing and moves down by a.

z2 168 $a[2]$. Same as *z1*, but a is two bytes long, $-32768 \le a < 32768$.

z3 169 $a[3]$. Same as *z1*, but a is three bytes long, $-2^{23} \le a < 2^{23}$.

z4 170 $a[4]$. Same as *z1*, but a is four bytes long, $-2^{31} \le a < 2^{31}$.

fnt_num_0 171. Set $f \leftarrow 0$. Font 0 must previously have been defined by a *fnt_def* instruction, as explained below.

fnt_num_1 through *fnt_num_63* (opcodes 172 to 234). Set $f \leftarrow 1$, ..., $f \leftarrow 63$, respectively.

fnt1 235 $k[1]$. Set $f \leftarrow k$. TEX82 uses this command for font numbers in the range $64 \le k < 256$.

fnt2 236 $k[2]$. Same as *fnt1*, except that k is two bytes long, so it is in the range $0 \le k < 65536$. TEX82 never generates this command, but large font numbers may prove useful for specifications of color or texture, or they may be used for special fonts that have fixed numbers in some external coding scheme.

fnt3 237 $k[3]$. Same as *fnt1*, except that k is three bytes long, so it can be as large as $2^{24} - 1$.

fnt4 238 $k[4]$. Same as *fnt1*, except that k is four bytes long; this is for the really big font numbers (and for the negative ones).

xxx1 239 $k[1]$ $x[k]$. This command is undefined in general; it functions as a $(k + 2)$-byte *nop* unless special DVI-reading programs are being used. TEX82 generates *xxx1* when a short enough \special appears, setting k to the number of bytes being sent. It is recommended that x be a string having the form of a keyword followed by possible parameters relevant to that keyword.

xxx2 240 $k[2]$ $x[k]$. Like *xxx1*, but $0 \le k < 65536$.

xxx3 241 $k[3]$ $x[k]$. Like *xxx1*, but $0 \le k < 2^{24}$.

xxx4 242 $k[4]$ $x[k]$. Like *xxx1*, but k can be ridiculously large. TEX82 uses *xxx4* when sending a string of length 256 or more.

fnt_def1 243 $k[1]$ $c[4]$ $s[4]$ $d[4]$ $a[1]$ $l[1]$ $n[a + l]$. Define font k, where $0 \le k < 256$; font definitions will be explained shortly.

fnt_def2 244 $k[2]$ $c[4]$ $s[4]$ $d[4]$ $a[1]$ $l[1]$ $n[a + l]$. Define font k, where $0 \le k < 65536$.

fnt_def3 245 $k[3]$ $c[4]$ $s[4]$ $d[4]$ $a[1]$ $l[1]$ $n[a + l]$. Define font k, where $0 \le k < 2^{24}$.

fnt_def4 246 $k[4]$ $c[4]$ $s[4]$ $d[4]$ $a[1]$ $l[1]$ $n[a + l]$. Define font k, where $-2^{31} \le k < 2^{31}$.

pre 247 $i[1]$ *num*$[4]$ *den*$[4]$ *mag*$[4]$ $k[1]$ $x[k]$. Beginning of the preamble; this must come at the very beginning of the file. Parameters i, *num*, *den*, *mag*, k, and x are explained below.

post 248. Beginning of the postamble, see below.

post_post 249. Ending of the postamble, see below.

Commands 250–255 are undefined in normal DVI files, but the following commands are used in XDV files.

define_native_font 252 $k[4]$ $s[4]$ *flags*$[2]$ $l[1]$ $n[l]$ $i[4]$
$$\textbf{if } (\textit{flags} \wedge \textit{COLORED}) \textbf{ then } \textit{rgba}[4]$$
$$\textbf{if } (\textit{flags} \wedge \textit{EXTEND}) \textbf{ then } \textit{extend}[4]$$
$$\textbf{if } (\textit{flags} \wedge \textit{SLANT}) \textbf{ then } \textit{slant}[4]$$
$$\textbf{if } (\textit{flags} \wedge \textit{EMBOLDEN}) \textbf{ then } \textit{embolden}[4]$$

set_glyphs 253 $w[4]$ $k[2]$ $xy[8k]$ $g[2k]$.

set_text_and_glyphs 254 $l[2]$ $t[2l]$ $w[4]$ $k[2]$ $xy[8k]$ $g[2k]$.

Commands 250 and 255 are undefined in normal XDV files.

622.   **define** $set\_char\_0 = 0$ { typeset character 0 and move right }
  define $set1 = 128$ { typeset a character and move right }

  define $post\_post = 249$ { postamble ending }
  define $define\_native\_font = 252$ { define native font }
  define $set\_glyphs = 253$ { sequence of glyphs with individual x-y coordinates }
  define $set\_text\_and\_glyphs = 254$ { run of Unicode (UTF16) text followed by positioned glyphs }

623.   The preamble contains basic information about the file as a whole. As stated above, there are six
parameters:

$$i[1]\ num[4]\ den[4]\ mag[4]\ k[1]\ x[k].$$

The i byte identifies DVI format; in X_{Ǝ}TEX this byte is set to 7, as we have new DVI opcodes, while in TEX82
it is always set to 2. (The value $i = 3$ is used for an extended format that allows a mixture of right-to-left
and left-to-right typesetting. Older versions of X_{Ǝ}TEX used $i = 4$, $i = 5$ and $i = 6$.)
    The next two parameters, num and den, are positive integers that define the units of measurement; they
are the numerator and denominator of a fraction by which all dimensions in the DVI file could be multiplied
in order to get lengths in units of 10^{-7} meters. Since 7227pt = 254cm, and since TEX works with scaled
points where there are 2^{16} sp in a point, TEX sets $num/den = (254 \cdot 10^5)/(7227 \cdot 2^{16}) = 25400000/473628672$.
    The mag parameter is what TEX calls \mag, i.e., 1000 times the desired magnification. The actual fraction
by which dimensions are multiplied is therefore $mag \cdot num/1000den$. Note that if a TEX source document
does not call for any 'true' dimensions, and if you change it only by specifying a different \mag setting, the
DVI file that TEX creates will be completely unchanged except for the value of mag in the preamble and
postamble. (Fancy DVI-reading programs allow users to override the mag setting when a DVI file is being
printed.)
    Finally, k and x allow the DVI writer to include a comment, which is not interpreted further. The length
of comment x is k, where $0 \le k < 256$.

  define $id\_byte = 7$ { identifies the kind of DVI files described here }

624.   Font definitions for a given font number k contain further parameters

$$c[4]\ s[4]\ d[4]\ a[1]\ l[1]\ n[a+l].$$

The four-byte value c is the check sum that TEX found in the TFM file for this font; c should match the check sum of the font found by programs that read this DVI file.

Parameter s contains a fixed-point scale factor that is applied to the character widths in font k; font dimensions in TFM files and other font files are relative to this quantity, which is called the "at size" elsewhere in this documentation. The value of s is always positive and less than 2^{27}. It is given in the same units as the other DVI dimensions, i.e., in sp when TEX82 has made the file. Parameter d is similar to s; it is the "design size," and (like s) it is given in DVI units. Thus, font k is to be used at $mag \cdot s/1000d$ times its normal size.

The remaining part of a font definition gives the external name of the font, which is an ASCII string of length $a + l$. The number a is the length of the "area" or directory, and l is the length of the font name itself; the standard local system font area is supposed to be used when $a = 0$. The n field contains the area in its first a bytes.

Font definitions must appear before the first use of a particular font number. Once font k is defined, it must not be defined again; however, we shall see below that font definitions appear in the postamble as well as in the pages, so in this sense each font number is defined exactly twice, if at all. Like *nop* commands, font definitions can appear before the first *bop*, or between an *eop* and a *bop*.

625.   Sometimes it is desirable to make horizontal or vertical rules line up precisely with certain features in characters of a font. It is possible to guarantee the correct matching between DVI output and the characters generated by METAFONT by adhering to the following principles: (1) The METAFONT characters should be positioned so that a bottom edge or left edge that is supposed to line up with the bottom or left edge of a rule appears at the reference point, i.e., in row 0 and column 0 of the METAFONT raster. This ensures that the position of the rule will not be rounded differently when the pixel size is not a perfect multiple of the units of measurement in the DVI file. (2) A typeset rule of height $a > 0$ and width $b > 0$ should be equivalent to a METAFONT-generated character having black pixels in precisely those raster positions whose METAFONT coordinates satisfy $0 \le x < \alpha b$ and $0 \le y < \alpha a$, where α is the number of pixels per DVI unit.

626.   The last page in a DVI file is followed by '*post*'; this command introduces the postamble, which summarizes important facts that TEX has accumulated about the file, making it possible to print subsets of the data with reasonable efficiency. The postamble has the form

$$post\ p[4]\ num[4]\ den[4]\ mag[4]\ l[4]\ u[4]\ s[2]\ t[2]$$
$$\langle\,\text{font definitions}\,\rangle$$
$$post\_post\ q[4]\ i[1]\ 223\text{'s}[\ge 4]$$

Here p is a pointer to the final *bop* in the file. The next three parameters, *num*, *den*, and *mag*, are duplicates of the quantities that appeared in the preamble.

Parameters l and u give respectively the height-plus-depth of the tallest page and the width of the widest page, in the same units as other dimensions of the file. These numbers might be used by a DVI-reading program to position individual "pages" on large sheets of film or paper; however, the standard convention for output on normal size paper is to position each page so that the upper left-hand corner is exactly one inch from the left and the top. Experience has shown that it is unwise to design DVI-to-printer software that attempts cleverly to center the output; a fixed position of the upper left corner is easiest for users to understand and to work with. Therefore l and u are often ignored.

Parameter s is the maximum stack depth (i.e., the largest excess of *push* commands over *pop* commands) needed to process this file. Then comes t, the total number of pages (*bop* commands) present.

The postamble continues with font definitions, which are any number of *fnt_def* commands as described above, possibly interspersed with *nop* commands. Each font number that is used in the DVI file must be defined exactly twice: Once before it is first selected by a *fnt* command, and once in the postamble.

627. The last part of the postamble, following the *post_post* byte that signifies the end of the font definitions, contains q, a pointer to the *post* command that started the postamble. An identification byte, i, comes next; this currently equals 2, as in the preamble.

The i byte is followed by four or more bytes that are all equal to the decimal number 223 (i.e., ´337 in octal). T$_{E}$X puts out four to seven of these trailing bytes, until the total length of the file is a multiple of four bytes, since this works out best on machines that pack four bytes per word; but any number of 223's is allowed, as long as there are at least four of them. In effect, 223 is a sort of signature that is added at the very end.

This curious way to finish off a DVI file makes it feasible for DVI-reading programs to find the postamble first, on most computers, even though T$_{E}$X wants to write the postamble last. Most operating systems permit random access to individual words or bytes of a file, so the DVI reader can start at the end and skip backwards over the 223's until finding the identification byte. Then it can back up four bytes, read q, and move to byte q of the file. This byte should, of course, contain the value 248 (*post*); now the postamble can be read, so the DVI reader can discover all the information needed for typesetting the pages. Note that it is also possible to skip through the DVI file at reasonably high speed to locate a particular page, if that proves desirable. This saves a lot of time, since DVI files used in production jobs tend to be large.

Unfortunately, however, standard Pascal does not include the ability to access a random position in a file, or even to determine the length of a file. Almost all systems nowadays provide the necessary capabilities, so DVI format has been designed to work most efficiently with modern operating systems. But if DVI files have to be processed under the restrictions of standard Pascal, one can simply read them from front to back, since the necessary header information is present in the preamble and in the font definitions. (The l and u and s and t parameters, which appear only in the postamble, are "frills" that are handy but not absolutely necessary.)

628. Shipping pages out.   After considering T$_{\text{E}}$X's eyes and stomach, we come now to the bowels.

The *ship_out* procedure is given a pointer to a box; its mission is to describe that box in DVI form, outputting a "page" to *dvi_file*. The DVI coordinates $(h, v) = (0, 0)$ should correspond to the upper left corner of the box being shipped.

Since boxes can be inside of boxes inside of boxes, the main work of *ship_out* is done by two mutually recursive routines, *hlist_out* and *vlist_out*, which traverse the hlists and vlists inside of horizontal and vertical boxes.

As individual pages are being processed, we need to accumulate information about the entire set of pages, since such statistics must be reported in the postamble. The global variables *total_pages*, *max_v*, *max_h*, *max_push*, and *last_bop* are used to record this information.

The variable *doing_leaders* is *true* while leaders are being output. The variable *dead_cycles* contains the number of times an output routine has been initiated since the last *ship_out*.

A few additional global variables are also defined here for use in *vlist_out* and *hlist_out*. They could have been local variables, but that would waste stack space when boxes are deeply nested, since the values of these variables are not needed during recursive calls.

⟨ Global variables 13 ⟩ +≡
total_pages: *integer*;   { the number of pages that have been shipped out }
max_v: *scaled*;   { maximum height-plus-depth of pages shipped so far }
max_h: *scaled*;   { maximum width of pages shipped so far }
max_push: *integer*;   { deepest nesting of *push* commands encountered so far }
last_bop: *integer*;   { location of previous *bop* in the DVI output }
dead_cycles: *integer*;   { recent outputs that didn't ship anything out }
doing_leaders: *boolean*;   { are we inside a leader box? }

c, *f*: *quarterword*;   { character and font in current *char_node* }
rule_ht, *rule_dp*, *rule_wd*: *scaled*;   { size of current rule being output }
g: *pointer*;   { current glue specification }
lq, *lr*: *integer*;   { quantities used in calculations for leaders }

629.   ⟨ Set initial values of key variables 23 ⟩ +≡
  total_pages ← 0; *max_v* ← 0; *max_h* ← 0; *max_push* ← 0; *last_bop* ← −1; *doing_leaders* ← *false*;
  dead_cycles ← 0; *cur_s* ← −1;

630.   The DVI bytes are output to a buffer instead of being written directly to the output file. This makes it possible to reduce the overhead of subroutine calls, thereby measurably speeding up the computation, since output of DVI bytes is part of T$_{\text{E}}$X's inner loop. And it has another advantage as well, since we can change instructions in the buffer in order to make the output more compact. For example, a '*down2*' command can be changed to a '*y2*', thereby making a subsequent '*y0*' command possible, saving two bytes.

The output buffer is divided into two parts of equal size; the bytes found in *dvi_buf*[0 .. *half_buf* − 1] constitute the first half, and those in *dvi_buf*[*half_buf* .. *dvi_buf_size* − 1] constitute the second. The global variable *dvi_ptr* points to the position that will receive the next output byte. When *dvi_ptr* reaches *dvi_limit*, which is always equal to one of the two values *half_buf* or *dvi_buf_size*, the half buffer that is about to be invaded next is sent to the output and *dvi_limit* is changed to its other value. Thus, there is always at least a half buffer's worth of information present, except at the very beginning of the job.

Bytes of the DVI file are numbered sequentially starting with 0; the next byte to be generated will be number *dvi_offset* + *dvi_ptr*. A byte is present in the buffer only if its number is ≥ *dvi_gone*.

⟨ Types in the outer block 18 ⟩ +≡
  dvi_index = 0 .. *dvi_buf_size*;   { an index into the output buffer }

631. Some systems may find it more efficient to make *dvi_buf* a **packed** array, since output of four bytes at once may be facilitated.

⟨Global variables 13⟩ +≡

dvi_buf: **array** [*dvi_index*] **of** *eight_bits*;   { buffer for DVI output }

half_buf: *dvi_index*;   { half of *dvi_buf_size* }

dvi_limit: *dvi_index*;   { end of the current half buffer }

dvi_ptr: *dvi_index*;   { the next available buffer address }

dvi_offset: *integer*;   { *dvi_buf_size* times the number of times the output buffer has been fully emptied }

dvi_gone: *integer*;   { the number of bytes already output to *dvi_file* }

632. Initially the buffer is all in one piece; we will output half of it only after it first fills up.

⟨Set initial values of key variables 23⟩ +≡

  half_buf ← *dvi_buf_size* **div** 2; *dvi_limit* ← *dvi_buf_size*; *dvi_ptr* ← 0; *dvi_offset* ← 0; *dvi_gone* ← 0;

633. The actual output of *dvi_buf* [*a* . . *b*] to *dvi_file* is performed by calling *write_dvi*(*a, b*). For best results, this procedure should be optimized to run as fast as possible on each particular system, since it is part of TEX's inner loop. It is safe to assume that *a* and *b* + 1 will both be multiples of 4 when *write_dvi*(*a, b*) is called; therefore it is possible on many machines to use efficient methods to pack four bytes per word and to output an array of words with one system call.

procedure *write_dvi*(*a, b* : *dvi_index*);

  var *k*: *dvi_index*;

  begin for *k* ← *a* **to** *b* **do** *write*(*dvi_file*, *dvi_buf* [*k*]);

  end;

634. To put a byte in the buffer without paying the cost of invoking a procedure each time, we use the macro *dvi_out*.

  define *dvi_out*(#) ≡ **begin** *dvi_buf* [*dvi_ptr*] ← #; *incr*(*dvi_ptr*);

        if *dvi_ptr* = *dvi_limit* **then** *dvi_swap*;

        end

procedure *dvi_swap*;   { outputs half of the buffer }

  begin if *dvi_limit* = *dvi_buf_size* **then**

    begin *write_dvi*(0, *half_buf* − 1); *dvi_limit* ← *half_buf*; *dvi_offset* ← *dvi_offset* + *dvi_buf_size*;

    dvi_ptr ← 0;

    end

  else begin *write_dvi*(*half_buf*, *dvi_buf_size* − 1); *dvi_limit* ← *dvi_buf_size*;

    end;

  dvi_gone ← *dvi_gone* + *half_buf*;

  end;

635. Here is how we clean out the buffer when TEX is all through; *dvi_ptr* will be a multiple of 4.

⟨Empty the last bytes out of *dvi_buf* 635⟩ ≡

  if *dvi_limit* = *half_buf* **then** *write_dvi*(*half_buf*, *dvi_buf_size* − 1);

  if *dvi_ptr* > 0 **then** *write_dvi*(0, *dvi_ptr* − 1)

This code is used in section 680.

636. The *dvi_four* procedure outputs four bytes in two's complement notation, without risking arithmetic overflow.

procedure *dvi_four* (*x* : *integer*);
  begin if $x \geq 0$ **then** *dvi_out* (*x* **div** ´100000000´)
  else begin $x \leftarrow x + $´10000000000´; $x \leftarrow x + $´10000000000´; *dvi_out* ((*x* **div** ´100000000´) + 128);
    end;
  $x \leftarrow x$ **mod** ´100000000´; *dvi_out* (*x* **div** ´200000´); $x \leftarrow x$ **mod** ´200000´; *dvi_out* (*x* **div** ´400´);
  dvi_out (*x* **mod** ´400´);
  end;
procedure *dvi_two* (*s* : *UTF16_code*);
  begin *dvi_out* (*s* **div** ´400´); *dvi_out* (*s* **mod** ´400´);
  end;

637. A mild optimization of the output is performed by the *dvi_pop* routine, which issues a *pop* unless it is possible to cancel a '*push pop*' pair. The parameter to *dvi_pop* is the byte address following the old *push* that matches the new *pop*.

procedure *dvi_pop* (*l* : *integer*);
  begin if $(l = dvi\_offset + dvi\_ptr) \wedge (dvi\_ptr > 0)$ **then** *decr* (*dvi_ptr*)
  else *dvi_out* (*pop*);
  end;

638. Here's a procedure that outputs a font definition. Since TEX82 uses at most 256 different fonts per job, *fnt_def1* is always used as the command code.

procedure *dvi_native_font_def* (*f* : *internal_font_number*);
  var *font_def_length*, *i*: *integer*;
  begin *dvi_out* (*define_native_font*); *dvi_four* (*f* − *font_base* − 1); *font_def_length* ← *make_font_def* (*f*);
  for *i* ← 0 **to** *font_def_length* − 1 **do** *dvi_out* (*xdv_buffer* [*i*]);
  end;
procedure *dvi_font_def* (*f* : *internal_font_number*);
  var *k*: *pool_pointer*;   { index into *str_pool* }
    l: *integer*;   { length of name without mapping option }
    begin if *is_native_font* (*f*) **then** *dvi_native_font_def* (*f*)
    else begin *dvi_out* (*fnt_def1*); *dvi_out* (*f* − *font_base* − 1);
      dvi_out (*qo*(*font_check* [*f*].*b0*)); *dvi_out* (*qo*(*font_check* [*f*].*b1*)); *dvi_out* (*qo*(*font_check* [*f*].*b2*));
      dvi_out (*qo*(*font_check* [*f*].*b3*));
      dvi_four (*font_size* [*f*]); *dvi_four* (*font_dsize* [*f*]);
      dvi_out (*length*(*font_area* [*f*])); ⟨ Output the font name whose internal number is *f* 639 ⟩;
      end;

639. ⟨Output the font name whose internal number is f 639⟩ ≡
 $l \leftarrow 0$; $k \leftarrow str\_start\_macro(font\_name[f])$;   {search for colon; we will truncate the name there}
 while $(l = 0) \wedge (k < str\_start\_macro(font\_name[f] + 1))$ **do**
  begin if $so(str\_pool[k]) = \texttt{":"}$ **then** $l \leftarrow k - str\_start\_macro(font\_name[f])$;
  $incr(k)$;
  end;
 if $l = 0$ **then** $l \leftarrow length(font\_name[f])$;   {no colon found}
 $dvi\_out(l)$;
 for $k \leftarrow str\_start\_macro(font\_area[f])$ **to** $str\_start\_macro(font\_area[f] + 1) - 1$ **do**
  $dvi\_out(so(str\_pool[k]))$;
 for $k \leftarrow str\_start\_macro(font\_name[f])$ **to** $str\_start\_macro(font\_name[f]) + l - 1$ **do**
  $dvi\_out(so(str\_pool[k]))$;
 end ;

This code is used in section 638.

640.   Versions of T_EX intended for small computers might well choose to omit the ideas in the next few parts of this program, since it is not really necessary to optimize the DVI code by making use of the $w0$, $x0$, $y0$, and $z0$ commands. Furthermore, the algorithm that we are about to describe does not pretend to give an optimum reduction in the length of the DVI code; after all, speed is more important than compactness. But the method is surprisingly effective, and it takes comparatively little time.

  We can best understand the basic idea by first considering a simpler problem that has the same essential characteristics. Given a sequence of digits, say 3 1 4 1 5 9 2 6 5 3 5 8 9, we want to assign subscripts d, y, or z to each digit so as to maximize the number of "y-hits" and "z-hits"; a y-hit is an instance of two appearances of the same digit with the subscript y, where no y's intervene between the two appearances, and a z-hit is defined similarly. For example, the sequence above could be decorated with subscripts as follows:

$$3_z\, 1_y\, 4_d\, 1_y\, 5_y\, 9_d\, 2_d\, 6_d\, 5_y\, 3_z\, 5_y\, 8_d\, 9_d.$$

There are three y-hits ($1_y \ldots 1_y$ and $5_y \ldots 5_y \ldots 5_y$) and one z-hit ($3_z \ldots 3_z$); there are no d-hits, since the two appearances of 9_d have d's between them, but we don't count d-hits so it doesn't matter how many there are. These subscripts are analogous to the DVI commands called $down$, y, and z, and the digits are analogous to different amounts of vertical motion; a y-hit or z-hit corresponds to the opportunity to use the one-byte commands $y0$ or $z0$ in a DVI file.

  T_EX's method of assigning subscripts works like this: Append a new digit, say δ, to the right of the sequence. Now look back through the sequence until one of the following things happens: (a) You see δ_y or δ_z, and this was the first time you encountered a y or z subscript, respectively. Then assign y or z to the new δ; you have scored a hit. (b) You see δ_d, and no y subscripts have been encountered so far during this search. Then change the previous δ_d to δ_y (this corresponds to changing a command in the output buffer), and assign y to the new δ; it's another hit. (c) You see δ_d, and a y subscript has been seen but not a z. Change the previous δ_d to δ_z and assign z to the new δ. (d) You encounter both y and z subscripts before encountering a suitable δ, or you scan all the way to the front of the sequence. Assign d to the new δ; this assignment may be changed later.

  The subscripts $3_z\, 1_y\, 4_d \ldots$ in the example above were, in fact, produced by this procedure, as the reader can verify. (Go ahead and try it.)

641. In order to implement such an idea, TEX maintains a stack of pointers to the *down*, *y*, and *z* commands that have been generated for the current page. And there is a similar stack for *right*, *w*, and *x* commands. These stacks are called the down stack and right stack, and their top elements are maintained in the variables *down_ptr* and *right_ptr*.

Each entry in these stacks contains four fields: The *width* field is the amount of motion down or to the right; the *location* field is the byte number of the DVI command in question (including the appropriate *dvi_offset*); the *link* field points to the next item below this one on the stack; and the *info* field encodes the options for possible change in the DVI command.

> **define** *movement_node_size* = 3   { number of words per entry in the down and right stacks }
> **define** *location*(#) ≡ *mem*[# + 2].*int*   { DVI byte number for a movement command }

⟨ Global variables 13 ⟩ +≡
down_ptr, *right_ptr*: *pointer*;   { heads of the down and right stacks }

642. ⟨ Set initial values of key variables 23 ⟩ +≡
  down_ptr ← *null*; *right_ptr* ← *null*;

643. Here is a subroutine that produces a DVI command for some specified downward or rightward motion. It has two parameters: *w* is the amount of motion, and *o* is either *down1* or *right1*. We use the fact that the command codes have convenient arithmetic properties: $y1 - down1 = w1 - right1$ and $z1 - down1 = x1 - right1$.

procedure *movement*(*w* : *scaled*; *o* : *eight_bits*);
  label *exit*, *found*, *not_found*, 2, 1;
  var *mstate*: *small_number*;   { have we seen a *y* or *z*? }
    p, *q*: *pointer*;   { current and top nodes on the stack }
    k: *integer*;   { index into *dvi_buf*, modulo *dvi_buf_size* }
  begin *q* ← *get_node*(*movement_node_size*);   { new node for the top of the stack }
  width(*q*) ← *w*; *location*(*q*) ← *dvi_offset* + *dvi_ptr*;
  if *o* = *down1* **then**
    begin *link*(*q*) ← *down_ptr*; *down_ptr* ← *q*;
    end
  else begin *link*(*q*) ← *right_ptr*; *right_ptr* ← *q*;
    end;
  ⟨ Look at the other stack entries until deciding what sort of DVI command to generate; **goto** *found* if node *p* is a "hit" 647 ⟩;
  ⟨ Generate a *down* or *right* command for *w* and **return** 646 ⟩;
found: ⟨ Generate a *y0* or *z0* command in order to reuse a previous appearance of *w* 645 ⟩;
exit: **end**;

644. The *info* fields in the entries of the down stack or the right stack have six possible settings: *y_here* or *z_here* mean that the DVI command refers to y or z, respectively (or to w or x, in the case of horizontal motion); *yz_OK* means that the DVI command is *down* (or *right*) but can be changed to either y or z (or to either w or x); *y_OK* means that it is *down* and can be changed to y but not z; *z_OK* is similar; and *d_fixed* means it must stay *down*.

The four settings *yz_OK*, *y_OK*, *z_OK*, *d_fixed* would not need to be distinguished from each other if we were simply solving the digit-subscripting problem mentioned above. But in TEX's case there is a complication because of the nested structure of *push* and *pop* commands. Suppose we add parentheses to the digit-subscripting problem, redefining hits so that $\delta_y \ldots \delta_y$ is a hit if all y's between the δ's are enclosed in properly nested parentheses, and if the parenthesis level of the right-hand δ_y is deeper than or equal to that of the left-hand one. Thus, '(' and ')' correspond to '*push*' and '*pop*'. Now if we want to assign a subscript to the final 1 in the sequence

$$2_y \, 7_d \, 1_d \, (\, 8_z \, 2_y \, 8_z \,) \, 1$$

we cannot change the previous 1_d to 1_y, since that would invalidate the $2_y \ldots 2_y$ hit. But we can change it to 1_z, scoring a hit since the intervening 8_z's are enclosed in parentheses.

The program below removes movement nodes that are introduced after a *push*, before it outputs the corresponding *pop*.

> **define** *y_here* = 1   { *info* when the movement entry points to a y command }
> **define** *z_here* = 2   { *info* when the movement entry points to a z command }
> **define** *yz_OK* = 3   { *info* corresponding to an unconstrained *down* command }
> **define** *y_OK* = 4   { *info* corresponding to a *down* that can't become a z }
> **define** *z_OK* = 5   { *info* corresponding to a *down* that can't become a y }
> **define** *d_fixed* = 6   { *info* corresponding to a *down* that can't change }

645. When the *movement* procedure gets to the label *found*, the value of *info*(p) will be either *y_here* or *z_here*. If it is, say, *y_here*, the procedure generates a *y0* command (or a *w0* command), and marks all *info* fields between q and p so that y is not OK in that range.

⟨ Generate a *y0* or *z0* command in order to reuse a previous appearance of w 645 ⟩ ≡
  info(q) ← *info*(p);
  if *info*(q) = *y_here* **then**
    begin *dvi_out*(o + *y0* − *down1*);   { *y0* or *w0* }
    while *link*(q) ≠ p **do**
      begin q ← *link*(q);
      case *info*(q) **of**
      yz_OK: *info*(q) ← *z_OK*;
      y_OK: *info*(q) ← *d_fixed*;
      othercases *do_nothing*
      endcases;
      end;
    end
  else begin *dvi_out*(o + *z0* − *down1*);   { *z0* or *x0* }
    while *link*(q) ≠ p **do**
      begin q ← *link*(q);
      case *info*(q) **of**
      yz_OK: *info*(q) ← *y_OK*;
      z_OK: *info*(q) ← *d_fixed*;
      othercases *do_nothing*
      endcases;
      end;
    end

This code is used in section 643.

646. ⟨Generate a *down* or *right* command for w and **return** 646⟩ ≡
  $info(q) \leftarrow yz\_OK$;
  if $abs(w) \geq$ ´40000000 **then**
    begin $dvi\_out(o + 3)$; { *down4* or *right4* }
    $dvi\_four(w)$; **return**;
    end;
  if $abs(w) \geq$ ´100000 **then**
    begin $dvi\_out(o + 2)$; { *down3* or *right3* }
    if $w < 0$ **then** $w \leftarrow w +$ ´100000000;
    $dvi\_out(w$ **div** ´200000$)$; $w \leftarrow w$ **mod** ´200000; **goto** 2;
    end;
  if $abs(w) \geq$ ´200 **then**
    begin $dvi\_out(o + 1)$; { *down2* or *right2* }
    if $w < 0$ **then** $w \leftarrow w +$ ´200000;
    goto 2;
    end;
  $dvi\_out(o)$; { *down1* or *right1* }
  if $w < 0$ **then** $w \leftarrow w +$ ´400;
  goto 1;
2: $dvi\_out(w$ **div** ´400$)$;
1: $dvi\_out(w$ **mod** ´400$)$; **return**

This code is used in section 643.

647.   As we search through the stack, we are in one of three states, *y_seen*, *z_seen*, or *none_seen*, depending on whether we have encountered *y_here* or *z_here* nodes. These states are encoded as multiples of 6, so that they can be added to the *info* fields for quick decision-making.

  define *none_seen* = 0   { no *y_here* or *z_here* nodes have been encountered yet }
  define *y_seen* = 6   { we have seen *y_here* but not *z_here* }
  define *z_seen* = 12   { we have seen *z_here* but not *y_here* }

  begin $k \leftarrow location(p) - dvi\_offset$;
  if $k < 0$ **then** $k \leftarrow k + dvi\_buf\_size$;
  $dvi\_buf[k] \leftarrow dvi\_buf[k] + z1 - down1$; $info(p) \leftarrow z\_here$; **goto** *found*;
  end

This code is used in section 648.

651. In case you are wondering when all the movement nodes are removed from T$_{E}$X's memory, the answer is that they are recycled just before *hlist_out* and *vlist_out* finish outputting a box. This restores the down and right stacks to the state they were in before the box was output, except that some *info*'s may have become more restrictive.

procedure *prune_movements*(*l* : *integer*);   { delete movement nodes with *location* ≥ *l* }
  label *done*, *exit*;
  var *p*: *pointer*;   { node being deleted }
  begin while *down_ptr* ≠ *null* **do**

    $p \leftarrow down\_ptr$; $down\_ptr \leftarrow link(p)$; *free_node*(*p*, *movement_node_size*);
    end;
done: **while** *right_ptr* ≠ *null* **do**
    begin if *location*(*right_ptr*) < *l* **then return**;
    $p \leftarrow right\_ptr$; $right\_ptr \leftarrow link(p)$; *free_node*(*p*, *movement_node_size*);
    end;
exit: **end**;

652.   The actual distances by which we want to move might be computed as the sum of several separate movements. For example, there might be several glue nodes in succession, or we might want to move right by the width of some box plus some amount of glue. More importantly, the baselineskip distances are computed in terms of glue together with the depth and height of adjacent boxes, and we want the DVI file to lump these three quantities together into a single motion.

Therefore, T$_{\rm E}$X maintains two pairs of global variables: *dvi_h* and *dvi_v* are the *h* and *v* coordinates corresponding to the commands actually output to the DVI file, while *cur_h* and *cur_v* are the coordinates corresponding to the current state of the output routines. Coordinate changes will accumulate in *cur_h* and *cur_v* without being reflected in the output, until such a change becomes necessary or desirable; we can call the *movement* procedure whenever we want to make $dvi\_h = cur\_h$ or $dvi\_v = cur\_v$.

The current font reflected in the DVI output is called *dvi_f*; there is no need for a '*cur_f*' variable.

The depth of nesting of *hlist_out* and *vlist_out* is called *cur_s*; this is essentially the depth of *push* commands in the DVI output.

For mixed direction text (T$_{\rm E}$X--X$_{\exists}$T) the current text direction is called *cur_dir*. As the box being shipped out will never be used again and soon be recycled, we can simply reverse any R-text (i.e., right-to-left) segments of hlist nodes as well as complete hlist nodes embedded in such segments. Moreover this can be done iteratively rather than recursively. There are, however, two complications related to leaders that require some additional bookkeeping: (1) One and the same hlist node might be used more than once (but never inside both L- and R-text); and (2) leader boxes inside hlists must be aligned with respect to the left edge of the original hlist.

A math node is changed into a kern node whenever the text direction remains the same, it is replaced by an *edge_node* if the text direction changes; the subtype of an an *hlist_node* inside R-text is changed to *reversed* once its hlist has been reversed.

> **define** *reversed* = 1   { subtype for an *hlist_node* whose hlist has been reversed }
> **define** *dlist* = 2   { subtype for an *hlist_node* from display math mode }

    end

This code is used in section 678.

654.   When *hlist_out* is called, its duty is to output the box represented by the *hlist_node* pointed to by
temp_ptr. The reference point of that box has coordinates (cur_h, cur_v).

   Similarly, when *vlist_out* is called, its duty is to output the box represented by the *vlist_node* pointed to
by *temp_ptr*. The reference point of that box has coordinates (cur_h, cur_v).

procedure *vlist_out*; *forward*;   { *hlist_out* and *vlist_out* are mutually recursive }

655.   The recursive procedures *hlist_out* and *vlist_out* each have local variables *save_h* and *save_v* to hold the values of *dvi_h* and *dvi_v* just before entering a new level of recursion. In effect, the values of *save_h* and *save_v* on TEX's run-time stack correspond to the values of *h* and *v* that a DVI-reading program will push onto its coordinate stack.

     else $cur\_h \leftarrow edge - 10;$

     goto $next\_p;$

     end;

  end

This code is used in section 663.

665.   The calculations related to leaders require a bit of care. First, in the case of *a_leaders* (aligned leaders),
we want to move *cur_h* to *left_edge* plus the smallest multiple of *leader_wd* for which the result is not less than
the current value of *cur_h*; i.e., *cur_h* should become $left\_edge + leader\_wd \times \lceil (cur\_h - left\_edge)/leader\_wd \rceil$.
The program here should work in all cases even though some implementations of Pascal give nonstandard
results for the **div** operation when *cur_h* is less than *left_edge*.

In the case of *c_leaders* (centered leaders), we want to increase *cur_h* by half of the excess space not
occupied by the leaders; and in the case of *x_leaders* (expanded leaders) we increase *cur_h* by $1/(q + 1)$ of
this excess space, where q is the number of times the leader box will be replicated. Slight inaccuracies in the
division might accumulate; half of this rounding error is placed at each end of the leaders.

⟨ Let *cur_h* be the position of the first box, and set *leader_wd* + *lx* to the spacing between corresponding
      parts of boxes 665 ⟩ ≡
  if *subtype*(*p*) = *a_leaders* **then**
    begin *save_h* ← *cur_h*; *cur_h* ← *left_edge* + *leader_wd* ∗ ((*cur_h* − *left_edge*) **div** *leader_wd*);
    if *cur_h* < *save_h* **then** *cur_h* ← *cur_h* + *leader_wd*;
    end
  else begin *lq* ← *rule_wd* **div** *leader_wd*;   { the number of box copies }
    lr ← *rule_wd* **mod** *leader_wd*;   { the remaining space }
    if *subtype*(*p*) = *c_leaders* **then** *cur_h* ← *cur_h* + (*lr* **div** 2)
    else begin *lx* ← *lr* **div** (*lq* + 1); *cur_h* ← *cur_h* + ((*lr* − (*lq* − 1) ∗ *lx*) **div** 2);
      end;
    end

This code is used in section 664.

666.   The '*synch*' operations here are intended to decrease the number of bytes needed to specify horizontal
and vertical motion in the DVI output.

⟨ Output a leader box at *cur_h*, then advance *cur_h* by *leader_wd* + *lx* 666 ⟩ ≡

    ⟨ Output the font definitions for all fonts that were used 681 ⟩;
    $dvi\_out(post\_post);$ $dvi\_four(last\_bop);$ $dvi\_out(id\_byte);$
    $k \leftarrow 4 + ((dvi\_buf\_size - dvi\_ptr)$ **mod** $4);$ { the number of 223's }
    while $k > 0$ **do**
      begin $dvi\_out(223);$ $decr(k);$
      end;
    ⟨ Empty the last bytes out of dvi_buf 635 ⟩;
    $print\_nl($"Output␣written␣on␣"$);$ $slow\_print(output\_file\_name);$ $print($"␣("$);$ $print\_int(total\_pages);$
    $print($"␣page"$);$
    if $total\_pages \neq 1$ **then** $print\_char($"s"$);$
    $print($",␣"$);$ $print\_int(dvi\_offset + dvi\_ptr);$ $print($"␣bytes)."$);$ $b\_close(dvi\_file);$
    end
This code is used in section 1387.

681. ⟨Output the font definitions for all fonts that were used 681 ⟩ ≡
　　while *font_ptr* > *font_base* **do**
　　　begin if *font_used*[*font_ptr*] **then** *dvi_font_def*(*font_ptr*);
　　　decr(*font_ptr*);
　　　end

This code is used in section 680.

682. pdfTEX output low-level subroutines (equivalents).

⟨ Global variables 13 ⟩ +≡
epochseconds: *integer* ;
microseconds: *integer* ;

683. Packaging. We're essentially done with the parts of TEX that are concerned with the input (*get_next*) and the output (*ship_out*). So it's time to get heavily into the remaining part, which does the real work of typesetting.

After lists are constructed, TEX wraps them up and puts them into boxes. Two major subroutines are given the responsibility for this task: *hpack* applies to horizontal lists (hlists) and *vpack* applies to vertical lists (vlists). The main duty of *hpack* and *vpack* is to compute the dimensions of the resulting boxes, and to adjust the glue if one of those dimensions is pre-specified. The computed sizes normally enclose all of the material inside the new box; but some items may stick out if negative glue is used, if the box is overfull, or if a \vbox includes other boxes that have been shifted left.

The subroutine call $hpack(p, w, m)$ returns a pointer to an *hlist_node* for a box containing the hlist that starts at p. Parameter w specifies a width; and parameter m is either '*exactly*' or '*additional*'. Thus, $hpack(p, w, exactly)$ produces a box whose width is exactly w, while $hpack(p, w, additional)$ yields a box whose width is the natural width plus w. It is convenient to define a macro called '*natural*' to cover the most common case, so that we can say $hpack(p, natural)$ to get a box that has the natural width of list p.

Similarly, $vpack(p, w, m)$ returns a pointer to a *vlist_node* for a box containing the vlist that starts at p. In this case w represents a height instead of a width; the parameter m is interpreted as in *hpack*.

> **define** $exactly = 0$ { a box dimension is pre-specified }
> **define** $additional = 1$ { a box dimension is increased from the natural one }
> **define** $natural \equiv 0, additional$ { shorthand for parameters to *hpack* and *vpack* }

684. The parameters to *hpack* and *vpack* correspond to TEX's primitives like '\hbox to 300pt', '\hbox spread 10pt'; note that '\hbox' with no dimension following it is equivalent to '\hbox spread 0pt'. The *scan_spec* subroutine scans such constructions in the user's input, including the mandatory left brace that follows them, and it puts the specification onto *save_stack* so that the desired box can later be obtained by executing the following code:

$$save\_ptr \leftarrow save\_ptr - 2;$$
$$hpack(p, saved(1), saved(0)).$$

Special care is necessary to ensure that the special *save_stack* codes are placed just below the new group code, because scanning can change *save_stack* when \csname appears.

procedure $scan\_spec(c : group\_code; three\_codes : boolean);$ { scans a box specification and left brace }
  label $found;$
  var s: $integer;$ { temporarily saved value }
    $spec\_code$: $exactly .. additional;$
  begin if $three\_codes$ **then** $s \leftarrow saved(0);$
  if $scan\_keyword(\texttt{"to"})$ **then** $spec\_code \leftarrow exactly$
  else if $scan\_keyword(\texttt{"spread"})$ **then** $spec\_code \leftarrow additional$
    else begin $spec\_code \leftarrow additional;$ $cur\_val \leftarrow 0;$ **goto** $found;$
      end;
  $scan\_normal\_dimen;$
$found$: **if** $three\_codes$ **then**
    begin $saved(0) \leftarrow s;$ $incr(save\_ptr);$
    end;
  $saved(0) \leftarrow spec\_code;$ $saved(1) \leftarrow cur\_val;$ $save\_ptr \leftarrow save\_ptr + 2;$ $new\_save\_level(c);$ $scan\_left\_brace;$
  end;

685. To figure out the glue setting, *hpack* and *vpack* determine how much stretchability and shrinkability are present, considering all four orders of infinity. The highest order of infinity that has a nonzero coefficient is then used as if no other orders were present.

For example, suppose that the given list contains six glue nodes with the respective stretchabilities 3pt, 8fill, 5fil, 6pt, −3fil, −8fill. Then the total is essentially 2fil; and if a total additional space of 6pt is to be achieved by stretching, the actual amounts of stretch will be 0pt, 0pt, 15pt, 0pt, −9pt, and 0pt, since only 'fil' glue will be considered. (The 'fill' glue is therefore not really stretching infinitely with respect to 'fil'; nobody would actually want that to happen.)

The arrays *total_stretch* and *total_shrink* are used to determine how much glue of each kind is present. A global variable *last_badness* is used to implement \badness.

⟨ Global variables 13 ⟩ +≡
total_stretch, *total_shrink*: **array** [*glue_ord*] **of** *scaled*;   { glue found by *hpack* or *vpack* }
last_badness: *integer*;   { badness of the most recently packaged box }

686. If the global variable *adjust_tail* is non-null, the *hpack* routine also removes all occurrences of *ins_node*, *mark_node*, and *adjust_node* items and appends the resulting material onto the list that ends at location *adjust_tail*.

⟨ Global variables 13 ⟩ +≡
adjust_tail: *pointer*;   { tail of adjustment list }

687. ⟨ Set initial values of key variables 23 ⟩ +≡
  adjust_tail ← *null*; *last_badness* ← 0;

688.   Some stuff for character protrusion.

> **define** $left\_pw(\#) \equiv char\_pw(\#, left\_side)$

This code is used in section 706.

710. The *vpack* subroutine is actually a special case of a slightly more general routine called *vpackage*, which has four parameters. The fourth parameter, which is *max_dimen* in the case of *vpack*, specifies the maximum depth of the page box that is constructed. The depth is first computed by the normal rules; if it exceeds this limit, the reference point is simply moved down until the limiting depth is attained.

  define *vpack*(#) ≡ *vpackage*(#, *max_dimen*)   {special case of unconstrained depth}

   else $prev\_depth \leftarrow depth(b)$;
   end;

722.   Data structures for math mode.   When TEX reads a formula that is enclosed between $'s, it constructs an *mlist*, which is essentially a tree structure representing that formula. An mlist is a linear sequence of items, but we can regard it as a tree structure because mlists can appear within mlists. For example, many of the entries can be subscripted or superscripted, and such "scripts" are mlists in their own right.

An entire formula is parsed into such a tree before any of the actual typesetting is done, because the current style of type is usually not known until the formula has been fully scanned. For example, when the formula '$a+b \over c+d$' is being read, there is no way to tell that 'a+b' will be in script size until '\over' has appeared.

During the scanning process, each element of the mlist being built is classified as a relation, a binary operator, an open parenthesis, etc., or as a construct like '\sqrt' that must be built up. This classification appears in the mlist data structure.

After a formula has been fully scanned, the mlist is converted to an hlist so that it can be incorporated into the surrounding text. This conversion is controlled by a recursive procedure that decides all of the appropriate styles by a "top-down" process starting at the outermost level and working in towards the subformulas. The formula is ultimately pasted together using combinations of horizontal and vertical boxes, with glue and penalty nodes inserted as necessary.

An mlist is represented internally as a linked list consisting chiefly of "noads" (pronounced "no-adds"), to distinguish them from the somewhat similar "nodes" in hlists and vlists. Certain kinds of ordinary nodes are allowed to appear in mlists together with the noads; TEX tells the difference by means of the *type* field, since a noad's *type* is always greater than that of a node. An mlist does not contain character nodes, hlist nodes, vlist nodes, math nodes, ligature nodes, or unset nodes; in particular, each mlist item appears in the variable-size part of *mem*, so the *type* field is always present.

723.   Each noad is four or more words long. The first word contains the *type* and *subtype* and *link* fields that are already so familiar to us; the second, third, and fourth words are called the noad's *nucleus*, *subscr*, and *supscr* fields.

Consider, for example, the simple formula '`$x^2$`', which would be parsed into an mlist containing a single element called an *ord_noad*. The *nucleus* of this noad is a representation of '`x`', the *subscr* is empty, and the *supscr* is a representation of '`2`'.

The *nucleus*, *subscr*, and *supscr* fields are further broken into subfields. If p points to a noad, and if q is one of its principal fields (e.g., $q = subscr(p)$), there are several possibilities for the subfields, depending on the *math_type* of q.

$math\_type(q) = math\_char$ means that $fam(q)$ refers to one of the sixteen font families, and $character(q)$ is the number of a character within a font of that family, as in a character node.

$math\_type(q) = math\_text\_char$ is similar, but the character is unsubscripted and unsuperscripted and it is followed immediately by another character from the same font. (This *math_type* setting appears only briefly during the processing; it is used to suppress unwanted italic corrections.)

$math\_type(q) = empty$ indicates a field with no value (the corresponding attribute of noad p is not present).

$math\_type(q) = sub\_box$ means that $info(q)$ points to a box node (either an *hlist_node* or a *vlist_node*) that should be used as the value of the field. The *shift_amount* in the subsidiary box node is the amount by which that box will be shifted downward.

$math\_type(q) = sub\_mlist$ means that $info(q)$ points to an mlist; the mlist must be converted to an hlist in order to obtain the value of this field.

In the latter case, we might have $info(q) = null$. This is not the same as $math\_type(q) = empty$; for example, '`$P_{}$`' and '`$P$`' produce different results (the former will not have the "italic correction" added to the width of P, but the "script skip" will be added).

The definitions of subfields given here are evidently wasteful of space, since a halfword is being used for the *math_type* although only three bits would be needed. However, there are hardly ever many noads present at once, since they are soon converted to nodes that take up even more space, so we can afford to represent them in whatever way simplifies the programming.

define *noad_size* = 4   { number of words in a normal noad }
define *nucleus*(#) ≡ # + 1   { the *nucleus* field of a noad }
define *supscr*(#) ≡ # + 2   { the *supscr* field of a noad }
define *subscr*(#) ≡ # + 3   { the *subscr* field of a noad }
define *math_type* ≡ *link*   { a *halfword* in *mem* }
define *plane_and_fam_field* ≡ *font*   { a *quarterword* in *mem* }
define *fam*(#) ≡ (*plane_and_fam_field*(#) **mod** ″100)
define *math_char* = 1   { *math_type* when the attribute is simple }
define *sub_box* = 2   { *math_type* when the attribute is a box }
define *sub_mlist* = 3   { *math_type* when the attribute is a formula }
define *math_text_char* = 4   { *math_type* when italic correction is dubious }

724. Each portion of a formula is classified as Ord, Op, Bin, Rel, Open, Close, Punct, or Inner, for purposes of spacing and line breaking. An *ord_noad*, *op_noad*, *bin_noad*, *rel_noad*, *open_noad*, *close_noad*, *punct_noad*, or *inner_noad* is used to represent portions of the various types. For example, an '=' sign in a formula leads to the creation of a *rel_noad* whose *nucleus* field is a representation of an equals sign (usually $fam = 0$, $character = ˝75$). A formula preceded by \mathrel also results in a *rel_noad*. When a *rel_noad* is followed by an *op_noad*, say, and possibly separated by one or more ordinary nodes (not noads), TEX will insert a penalty node (with the current *rel_penalty*) just after the formula that corresponds to the *rel_noad*, unless there already was a penalty immediately following; and a "thick space" will be inserted just before the formula that corresponds to the *op_noad*.

A noad of type *ord_noad*, *op_noad*, ..., *inner_noad* usually has a *subtype = normal*. The only exception is that an *op_noad* might have *subtype = limits* or *no_limits*, if the normal positioning of limits has been overridden for this operator.

    define *ord_noad* = *unset_node* + 3   { *type* of a noad classified Ord }
    define *op_noad* = *ord_noad* + 1   { *type* of a noad classified Op }
    define *bin_noad* = *ord_noad* + 2   { *type* of a noad classified Bin }
    define *rel_noad* = *ord_noad* + 3   { *type* of a noad classified Rel }
    define *open_noad* = *ord_noad* + 4   { *type* of a noad classified Open }
    define *close_noad* = *ord_noad* + 5   { *type* of a noad classified Close }
    define *punct_noad* = *ord_noad* + 6   { *type* of a noad classified Punct }
    define *inner_noad* = *ord_noad* + 7   { *type* of a noad classified Inner }
    define *limits* = 1   { *subtype* of *op_noad* whose scripts are to be above, below }
    define *no_limits* = 2   { *subtype* of *op_noad* whose scripts are to be normal }

725.   A *radical_noad* is five words long; the fifth word is the *left_delimiter* field, which usually represents a square root sign.

A *fraction_noad* is six words long; it has a *right_delimiter* field as well as a *left_delimiter*.

Delimiter fields are of type *four_quarters*, and they have four subfields called *small_fam*, *small_char*, *large_fam*, *large_char*. These subfields represent variable-size delimiters by giving the "small" and "large" starting characters, as explained in Chapter 17 of *The TEXbook*.

A *fraction_noad* is actually quite different from all other noads. Not only does it have six words, it has *thickness*, *denominator*, and *numerator* fields instead of *nucleus*, *subscr*, and *supscr*. The *thickness* is a scaled value that tells how thick to make a fraction rule; however, the special value *default_code* is used to stand for the *default_rule_thickness* of the current size. The *numerator* and *denominator* point to mlists that define a fraction; we always have

$$math\_type(numerator) = math\_type(denominator) = sub\_mlist.$$

The *left_delimiter* and *right_delimiter* fields specify delimiters that will be placed at the left and right of the fraction. In this way, a *fraction_noad* is able to represent all of TEX's operators \over, \atop, \above, \overwithdelims, \atopwithdelims, and \abovewithdelims.

define *left_delimiter*(#) ≡ # + 4   { first delimiter field of a noad }
define *right_delimiter*(#) ≡ # + 5   { second delimiter field of a fraction noad }
define *radical_noad* = *inner_noad* + 1   { *type* of a noad for square roots }
define *radical_noad_size* = 5   { number of *mem* words in a radical noad }
define *fraction_noad* = *radical_noad* + 1   { *type* of a noad for generalized fractions }
define *fraction_noad_size* = 6   { number of *mem* words in a fraction noad }
define *small_fam*(#) ≡ (*mem*[#].*qqqq.b0* **mod** ″100)   { *fam* for "small" delimiter }
define *small_char*(#) ≡ (*mem*[#].*qqqq.b1* + (*mem*[#].*qqqq.b0* **div** ″100) ∗ ″10000)
            { *character* for "small" delimiter }
define *large_fam*(#) ≡ (*mem*[#].*qqqq.b2* **mod** ″100)   { *fam* for "large" delimiter }
define *large_char*(#) ≡ (*mem*[#].*qqqq.b3* + (*mem*[#].*qqqq.b2* **div** ″100) ∗ ″10000)
            { *character* for "large" delimiter }
define *small_plane_and_fam_field*(#) ≡ *mem*[#].*qqqq.b0*
define *small_char_field*(#) ≡ *mem*[#].*qqqq.b1*
define *large_plane_and_fam_field*(#) ≡ *mem*[#].*qqqq.b2*
define *large_char_field*(#) ≡ *mem*[#].*qqqq.b3*
define *thickness* ≡ *width*   { *thickness* field in a fraction noad }
define *default_code* ≡ ′10000000000   { denotes *default_rule_thickness* }
define *numerator* ≡ *supscr*   { *numerator* field in a fraction noad }
define *denominator* ≡ *subscr*   { *denominator* field in a fraction noad }

726.   The global variable *empty_field* is set up for initialization of empty fields in new noads. Similarly, *null_delimiter* is for the initialization of delimiter fields.

⟨ Global variables 13 ⟩ +≡
empty_field: *two_halves*;
null_delimiter: *four_quarters*;

727.   ⟨ Set initial values of key variables 23 ⟩ +≡
  empty_field.rh ← *empty*; *empty_field.lh* ← *null*;
  null_delimiter.b0 ← 0; *null_delimiter.b1* ← *min_quarterword*;
  null_delimiter.b2 ← 0; *null_delimiter.b3* ← *min_quarterword*;

728.   The *new_noad* function creates an *ord_noad* that is completely null.

function *new_noad*: *pointer*;
  var *p*: *pointer*;
  begin $p \leftarrow get\_node(noad\_size)$; $type(p) \leftarrow ord\_noad$; $subtype(p) \leftarrow normal$;
  $mem[nucleus(p)].hh \leftarrow empty\_field$; $mem[subscr(p)].hh \leftarrow empty\_field$;
  $mem[supscr(p)].hh \leftarrow empty\_field$; $new\_noad \leftarrow p$;
  end;

729.   A few more kinds of noads will complete the set: An *under_noad* has its nucleus underlined; an *over_noad* has it overlined. An *accent_noad* places an accent over its nucleus; the accent character appears as $fam(accent\_chr(p))$ and $character(accent\_chr(p))$. A *vcenter_noad* centers its nucleus vertically with respect to the axis of the formula; in such noads we always have $math\_type(nucleus(p)) = sub\_box$.

And finally, we have *left_noad* and *right_noad* types, to implement TEX's \left and \right as well as ε-TEX's \middle. The *nucleus* of such noads is replaced by a *delimiter* field; thus, for example, '\left(' produces a *left_noad* such that $delimiter(p)$ holds the family and character codes for all left parentheses. A *left_noad* never appears in an mlist except as the first element, and a *right_noad* never appears in an mlist except as the last element; furthermore, we either have both a *left_noad* and a *right_noad*, or neither one is present. The *subscr* and *supscr* fields are always *empty* in a *left_noad* and a *right_noad*.

  define $under\_noad = fraction\_noad + 1$ { *type* of a noad for underlining }
  define $over\_noad = under\_noad + 1$ { *type* of a noad for overlining }
  define $accent\_noad = over\_noad + 1$ { *type* of a noad for accented subformulas }
  define $fixed\_acc = 1$ { *subtype* for non growing math accents }
  define $bottom\_acc = 2$ { *subtype* for bottom math accents }
  define $is\_bottom\_acc(\#) \equiv ((subtype(\#) = bottom\_acc) \vee (subtype(\#) = bottom\_acc + fixed\_acc))$
  define $accent\_noad\_size = 5$ { number of *mem* words in an accent noad }
  define $accent\_chr(\#) \equiv \# + 4$ { the *accent_chr* field of an accent noad }
  define $vcenter\_noad = accent\_noad + 1$ { *type* of a noad for \vcenter }
  define $left\_noad = vcenter\_noad + 1$ { *type* of a noad for \left }
  define $right\_noad = left\_noad + 1$ { *type* of a noad for \right }
  define $delimiter \equiv nucleus$ { *delimiter* field in left and right noads }
  define $middle\_noad \equiv 1$ { *subtype* of right noad representing \middle }
  define $scripts\_allowed(\#) \equiv (type(\#) \geq ord\_noad) \wedge (type(\#) < left\_noad)$

730.   Math formulas can also contain instructions like `\textstyle` that override TEX's normal style rules. A *style_node* is inserted into the data structure to record such instructions; it is three words long, so it is considered a node instead of a noad. The *subtype* is either *display_style* or *text_style* or *script_style* or *script_script_style*. The second and third words of a *style_node* are not used, but they are present because a *choice_node* is converted to a *style_node*.

TEX uses even numbers 0, 2, 4, 6 to encode the basic styles *display_style*, . . . , *script_script_style*, and adds 1 to get the "cramped" versions of these styles. This gives a numerical order that is backwards from the convention of Appendix G in *The TEXbook*; i.e., a smaller style has a larger numerical value.

define *style_node* = *unset_node* + 1   { *type* of a style node }
define *style_node_size* = 3   { number of words in a style node }
define *display_style* = 0   { *subtype* for `\displaystyle` }
define *text_style* = 2   { *subtype* for `\textstyle` }
define *script_style* = 4   { *subtype* for `\scriptstyle` }
define *script_script_style* = 6   { *subtype* for `\scriptscriptstyle` }
define *cramped* = 1   { add this to an uncramped style if you want to cramp it }

function *new_style*(*s* : *small_number*): *pointer*;   { create a style node }
  var *p*: *pointer*;   { the new node }
  begin *p* ← *get_node*(*style_node_size*); *type*(*p*) ← *style_node*; *subtype*(*p*) ← *s*; *width*(*p*) ← 0;
  depth(*p*) ← 0;   { the *width* and *depth* are not used }
  new_style ← *p*;
  end;

731.   Finally, the `\mathchoice` primitive creates a *choice_node*, which has special subfields *display_mlist*, *text_mlist*, *script_mlist*, and *script_script_mlist* pointing to the mlists for each style.

define *choice_node* = *unset_node* + 2   { *type* of a choice node }
define *display_mlist*(#) ≡ *info*(# + 1)   { mlist to be used in display style }
define *text_mlist*(#) ≡ *link*(# + 1)   { mlist to be used in text style }
define *script_mlist*(#) ≡ *info*(# + 2)   { mlist to be used in script style }
define *script_script_mlist*(#) ≡ *link*(# + 2)   { mlist to be used in scriptscript style }

function *new_choice*: *pointer*;   { create a choice node }
  var *p*: *pointer*;   { the new node }
  begin *p* ← *get_node*(*style_node_size*); *type*(*p*) ← *choice_node*; *subtype*(*p*) ← 0;
      { the *subtype* is not used }
  display_mlist(*p*) ← *null*; *text_mlist*(*p*) ← *null*; *script_mlist*(*p*) ← *null*; *script_script_mlist*(*p*) ← *null*;
  new_choice ← *p*;
  end;

732.   Let's consider now the previously unwritten part of *show_node_list* that displays the things that can only be present in mlists; this program illustrates how to access the data structures just defined.

In the context of the following program, p points to a node or noad that should be displayed, and the current string contains the "recursion history" that leads to this point. The recursion history consists of a dot for each outer level in which p is subsidiary to some node, or in which p is subsidiary to the *nucleus* field of some noad; the dot is replaced by '_' or '^' or '/' or '\' if p is descended from the *subscr* or *supscr* or *denominator* or *numerator* fields of noads. For example, the current string would be '.^._/' if p points to the *ord_noad* for x in the (ridiculous) formula '`$\sqrt{a^{\mathinner{b_{c\over x+y}}}}$`'.

⟨ Cases of *show_node_list* that arise in mlists only 732 ⟩ ≡
style_node: *print_style*(*subtype*(*p*));
choice_node: ⟨Display choice node *p* 737⟩;
ord_noad, *op_noad*, *bin_noad*, *rel_noad*, *open_noad*, *close_noad*, *punct_noad*,
    inner_noad, *radical_noad*, *over_noad*, *under_noad*, *vcenter_noad*, *accent_noad*, *left_noad*, *right_noad*:
    ⟨Display normal noad *p* 738⟩;
fraction_noad: ⟨Display fraction noad *p* 739⟩;

This code is used in section 209.

733.   Here are some simple routines used in the display of noads.

⟨ Declare procedures needed for displaying the elements of mlists 733 ⟩ ≡
procedure *print_fam_and_char*(*p* : *pointer*);   { prints family and character }
  var *c*: *integer*;
  begin *print_esc*("fam"); *print_int*(*fam*(*p*) **mod** ″100); *print_char*("␣");
  c ← (*cast_to_ushort*(*character*(*p*)) + ((*plane_and_fam_field*(*p*) **div** ″100) ∗ ″10000));
  if *c* < ″10000 **then** *print_ASCII*(*c*)
  else *print_char*(*c*);   { non-Plane 0 Unicodes can't be sent through *print_ASCII* }
  end;

procedure *print_delimiter*(*p* : *pointer*);   { prints a delimiter as 24-bit hex value }
  var *a*: *integer*;   { accumulator }
  begin *a* ← *small_fam*(*p*) ∗ 256 + *qo*(*small_char*(*p*));
  a ← *a* ∗ ″1000 + *large_fam*(*p*) ∗ 256 + *qo*(*large_char*(*p*));
  if *a* < 0 **then** *print_int*(*a*)   { this should never happen }
  else *print_hex*(*a*);
  end;

See also sections 734 and 736.

This code is used in section 205.

734. The next subroutine will descend to another level of recursion when a subsidiary mlist needs to be displayed. The parameter c indicates what character is to become part of the recursion history. An empty mlist is distinguished from a field with $math\_type(p) = empty$, because these are not equivalent (as explained above).

⟨Declare procedures needed for displaying the elements of mlists 733⟩ +≡
procedure $show\_info$; $forward$;   { $show\_node\_list(info(temp\_ptr))$ }
procedure $print\_subsidiary\_data(p : pointer; c : ASCII\_code)$;   {display a noad field}
  begin if $cur\_length \geq depth\_threshold$ **then**
    begin if $math\_type(p) \neq empty$ **then** $print("␣[]")$;
    end
  else begin $append\_char(c)$;   {include c in the recursion history}
    $temp\_ptr \leftarrow p$;   {prepare for $show\_info$ if recursion is needed}
    case $math\_type(p)$ **of**
    $math\_char$: **begin** $print\_ln$; $print\_current\_string$; $print\_fam\_and\_char(p)$;
      end;
    sub_box: $show\_info$;   {recursive call}
    sub_mlist: **if** $info(p) = null$ **then**
        begin $print\_ln$; $print\_current\_string$; $print("{}")$;
        end
      else $show\_info$;   {recursive call}
    othercases $do\_nothing$ {empty}
    endcases;
    $flush\_char$;   {remove c from the recursion history}
    end;
  end;

735. The inelegant introduction of $show\_info$ in the code above seems better than the alternative of using Pascal's strange $forward$ declaration for a procedure with parameters. The Pascal convention about dropping parameters from a post-$forward$ procedure is, frankly, so intolerable to the author of TEX that he would rather stoop to communication via a global temporary variable. (A similar stoopidity occurred with respect to $hlist\_out$ and $vlist\_out$ above, and it will occur with respect to $mlist\_to\_hlist$ below.)

procedure $show\_info$;   {the reader will kindly forgive this}
  begin $show\_node\_list(info(temp\_ptr))$;
  end;

736. ⟨Declare procedures needed for displaying the elements of mlists 733⟩ +≡
procedure $print\_style(c : integer)$;
  begin case c **div** 2 **of**
  0: $print\_esc("displaystyle")$;   { $display\_style = 0$ }
  1: $print\_esc("textstyle")$;   { $text\_style = 2$ }
  2: $print\_esc("scriptstyle")$;   { $script\_style = 4$ }
  3: $print\_esc("scriptscriptstyle")$;   { $script\_script\_style = 6$ }
  othercases $print("Unknown␣style!")$
  endcases;
  end;

737. ⟨Display choice node p 737⟩ ≡
> **begin** $print\_esc(\texttt{"mathchoice"})$; $append\_char(\texttt{"D"})$; $show\_node\_list(display\_mlist(p))$; $flush\_char$;

  $free\_node(p, fraction\_noad\_size)$; **goto** $done$;

  end;

This code is used in section 228.

741. Subroutines for math mode.   In order to convert mlists to hlists, i.e., noads to nodes, we need
several subroutines that are conveniently dealt with now.

Let us first introduce the macros that make it easy to get at the parameters and other font information. A
size code, which is a multiple of 16, is added to a family number to get an index into the table of internal font
numbers for each combination of family and size. (Be alert: Size codes get larger as the type gets smaller.)

⟨Basic printing procedures 57⟩ +≡
procedure *print_size*(*s* : *integer*);
  begin if *s* = *text_size* **then** *print_esc*("textfont")
  else if *s* = *script_size* **then** *print_esc*("scriptfont")
    else *print_esc*("scriptscriptfont");
  end;

742. Before an mlist is converted to an hlist, TEX makes sure that the fonts in family 2 have enough parameters to be math-symbol fonts, and that the fonts in family 3 have enough parameters to be math-extension fonts. The math-symbol parameters are referred to by using the following macros, which take a size code as their parameter; for example, $num1\,(cur\_size)$ gives the value of the $num1$ parameter for the current size.

NB: the access functions here must all put the font **#** into /f/ for mathsy().

The accessors are defined with $define\_mathsy\_accessor\,(NAME)(fontdimen - number)(NAME)$ because I can't see how to only give the name once, with WEB's limited macro capabilities. This seems a bit ugly, but it works.

> **define** $total\_mathsy\_params = 22$

745.   We also need to compute the change in style between mlists and their subsidiaries. The following
macros define the subsidiary style for an overlined nucleus (*cramped_style*), for a subscript or a superscript
(*sub_style* or *sup_style*), or for a numerator or denominator (*num_style* or *denom_style*).

 define *cramped_style*(#) ≡ 2 ∗ (# **div** 2) + *cramped* { cramp the style }
 define *sub_style*(#) ≡ 2 ∗ (# **div** 4) + *script_style* + *cramped* { smaller and cramped }
 define *sup_style*(#) ≡ 2 ∗ (# **div** 4) + *script_style* + (# **mod** 2) { smaller }
 define *num_style*(#) ≡ # + 2 − 2 ∗ (# **div** 6) { smaller unless already script-script }
 define *denom_style*(#) ≡ 2 ∗ (# **div** 2) + *cramped* + 2 − 2 ∗ (# **div** 6) { smaller, cramped }

746.   When the style changes, the following piece of program computes associated information:

⟨ Set up the values of *cur_size* and *cur_mu*, based on *cur_style* 746 ⟩ ≡
 begin if *cur_style* < *script_style* **then** *cur_size* ← *text_size*
 else *cur_size* ← *script_size* ∗ ((*cur_style* − *text_style*) **div** 2);
 cur_mu ← *x_over_n*(*math_quad*(*cur_size*), 18);
 end

This code is used in sections 763, 769, 770, 773, 798, 805, 805, 808, 810, and 811.

747.   Here is a function that returns a pointer to a rule node having a given thickness t. The rule will
extend horizontally to the boundary of the vlist that eventually contains it.

function *fraction_rule*(*t* : *scaled*): *pointer*; { construct the bar for a fraction }
 var *p*: *pointer*; { the new node }
 begin *p* ← *new_rule*; *height*(*p*) ← *t*; *depth*(*p*) ← 0; *fraction_rule* ← *p*;
 end;

748.   The *overbar* function returns a pointer to a vlist box that consists of a given box b, above which has
been placed a kern of height k under a fraction rule of thickness t under additional space of height t.

function *overbar*(*b* : *pointer*; *k*, *t* : *scaled*): *pointer*;
 var *p*, *q*: *pointer*; { nodes being constructed }
 begin *p* ← *new_kern*(*k*); *link*(*p*) ← *b*; *q* ← *fraction_rule*(*t*); *link*(*q*) ← *p*; *p* ← *new_kern*(*t*); *link*(*p*) ← *q*;
 overbar ← *vpack*(*p*, *natural*);
 end;

749. The *var_delimiter* function, which finds or constructs a sufficiently large delimiter, is the most interesting of the auxiliary functions that currently concern us. Given a pointer *d* to a delimiter field in some noad, together with a size code *s* and a vertical distance *v*, this function returns a pointer to a box that contains the smallest variant of *d* whose height plus depth is *v* or more. (And if no variant is large enough, it returns the largest available variant.) In particular, this routine will construct arbitrarily large delimiters from extensible components, if *d* leads to such characters.

The value returned is a box whose *shift_amount* has been set so that the box is vertically centered with respect to the axis in the given size. If a built-up symbol is returned, the height of the box before shifting will be the height of its topmost component.

        if $char\_tag(q) = list\_tag$ **then**
          begin $y \leftarrow rem\_byte(q)$; **goto** *continue*;
          end;
        end;
      end;
    end
This code is used in section 750.

752.   Here is a subroutine that creates a new box, whose list contains a single character, and whose width includes the italic correction for that character. The height or depth of the box will be negative, if the height or depth of the character is negative; thus, this routine may deliver a slightly different result than *hpack* would produce.

⟨ Declare subprocedures for *var_delimiter* 752 ⟩ ≡
function *char_box* (*f* : *internal_font_number* ; *c* : *integer*): *pointer* ;
  var *q*: *four_quarters* ; *hd* : *eight_bits* ;   { *height_depth* byte }
    b, p: *pointer* ;   { the new box and its character node }
  begin if *is_native_font* (*f*) **then**
    begin *b* ← *new_null_box* ; *p* ← *new_native_character* (*f, c*); *list_ptr* (*b*) ← *p* ; *height* (*b*) ← *height* (*p*);
    width (*b*) ← *width* (*p*);
    if *depth* (*p*) < 0 **then** *depth* (*b*) ← 0
    else *depth* (*b*) ← *depth* (*p*);
    end
  else begin *q* ← *char_info* (*f*)(*c*); *hd* ← *height_depth* (*q*); *b* ← *new_null_box* ;
    width (*b*) ← *char_width* (*f*)(*q*) + *char_italic* (*f*)(*q*); *height* (*b*) ← *char_height* (*f*)(*hd*);
    depth (*b*) ← *char_depth* (*f*)(*hd*); *p* ← *get_avail* ; *character* (*p*) ← *c* ; *font* (*p*) ← *f* ;
    end ;
  list_ptr (*b*) ← *p* ; *char_box* ← *b* ;
  end ;
See also sections 754 and 755.

This code is used in section 749.

753.   When the following code is executed, *char_tag* (*q*) will be equal to *ext_tag* if and only if a built-up symbol is supposed to be returned.

⟨ Make variable *b* point to a box for (*f, c*) 753 ⟩ ≡
  if *char_tag* (*q*) = *ext_tag* **then**
    ⟨ Construct an extensible character in a new box *b*, using recipe *rem_byte* (*q*) and font *f* 756 ⟩
  else *b* ← *char_box* (*f, c*)

This code is used in section 749.

754.   When we build an extensible character, it's handy to have the following subroutine, which puts a given character on top of the characters already in box *b*:

⟨ Declare subprocedures for *var_delimiter* 752 ⟩ +≡
procedure *stack_into_box* (*b* : *pointer* ; *f* : *internal_font_number* ; *c* : *quarterword*);
  var *p*: *pointer* ;   { new node placed into *b* }
  begin *p* ← *char_box* (*f, c*); *link* (*p*) ← *list_ptr* (*b*); *list_ptr* (*b*) ← *p* ; *height* (*b*) ← *height* (*p*);
  end ;

755.   Another handy subroutine computes the height plus depth of a given character:

⟨ Declare subprocedures for *var_delimiter* 752 ⟩ +≡
function *height_plus_depth* (*f* : *internal_font_number* ; *c* : *quarterword*): *scaled* ;
  var *q*: *four_quarters* ; *hd* : *eight_bits* ;   { *height_depth* byte }
  begin *q* ← *char_info* (*f*)(*c*); *hd* ← *height_depth* (*q*);
  height_plus_depth ← *char_height* (*f*)(*hd*) + *char_depth* (*f*)(*hd*);
  end ;

756. ⟨Construct an extensible character in a new box b, using recipe $rem\_byte(q)$ and font f 756⟩ ≡
  begin $b \leftarrow new\_null\_box$; $type(b) \leftarrow vlist\_node$; $r \leftarrow font\_info[exten\_base[f] + rem\_byte(q)].qqqq$;
  ⟨Compute the minimum suitable height, w, and the corresponding number of extension steps, n; also set
     $width(b)$ 757⟩;
  $c \leftarrow ext\_bot(r)$;
  if $c \neq min\_quarterword$ **then** $stack\_into\_box(b, f, c)$;
  $c \leftarrow ext\_rep(r)$;
  for $m \leftarrow 1$ **to** n **do** $stack\_into\_box(b, f, c)$;
  $c \leftarrow ext\_mid(r)$;
  if $c \neq min\_quarterword$ **then**
    begin $stack\_into\_box(b, f, c)$; $c \leftarrow ext\_rep(r)$;
    for $m \leftarrow 1$ **to** n **do** $stack\_into\_box(b, f, c)$;
    end;
  $c \leftarrow ext\_top(r)$;
  if $c \neq min\_quarterword$ **then** $stack\_into\_box(b, f, c)$;
  $depth(b) \leftarrow w - height(b)$;
  end

This code is used in section 753.

757. The width of an extensible character is the width of the repeatable module. If this module does not have positive height plus depth, we don't use any copies of it, otherwise we use as few as possible (in groups of two if there is a middle part).

⟨Compute the minimum suitable height, w, and the corresponding number of extension steps, n; also set
    $width(b)$ 757⟩ ≡
  $c \leftarrow ext\_rep(r)$; $u \leftarrow height\_plus\_depth(f, c)$; $w \leftarrow 0$; $q \leftarrow char\_info(f)(c)$;
  $width(b) \leftarrow char\_width(f)(q) + char\_italic(f)(q)$;
  $c \leftarrow ext\_bot(r)$; **if** $c \neq min\_quarterword$ **then** $w \leftarrow w + height\_plus\_depth(f, c)$;
  $c \leftarrow ext\_mid(r)$; **if** $c \neq min\_quarterword$ **then** $w \leftarrow w + height\_plus\_depth(f, c)$;
  $c \leftarrow ext\_top(r)$; **if** $c \neq min\_quarterword$ **then** $w \leftarrow w + height\_plus\_depth(f, c)$;
  $n \leftarrow 0$;
  if $u > 0$ **then**
    while $w < v$ **do**
      begin $w \leftarrow w + u$; $incr(n)$;
      if $ext\_mid(r) \neq min\_quarterword$ **then** $w \leftarrow w + u$;
      end

This code is used in section 756.

758.   The next subroutine is much simpler; it is used for numerators and denominators of fractions as well as for displayed operators and their limits above and below. It takes a given box b and changes it so that the new box is centered in a box of width w. The centering is done by putting \hss glue at the left and right of the list inside b, then packaging the new box; thus, the actual box might not really be centered, if it already contains infinite glue.

The given box might contain a single character whose italic correction has been added to the width of the box; in this case a compensating kern is inserted.

function $rebox(b : pointer; w : scaled): pointer;$
 var p: $pointer$; { temporary register for list manipulation }
  f: $internal\_font\_number$; { font in a one-character box }
  v: $scaled$; { width of a character without italic correction }
 begin if $(width(b) \neq w) \wedge (list\_ptr(b) \neq null)$ **then**
  begin if $type(b) = vlist\_node$ **then** $b \leftarrow hpack(b, natural)$;
  $p \leftarrow list\_ptr(b)$;
  if $(is\_char\_node(p)) \wedge (link(p) = null)$ **then**
   begin $f \leftarrow font(p)$; $v \leftarrow char\_width(f)(char\_info(f)(character(p)))$;
   if $v \neq width(b)$ **then** $link(p) \leftarrow new\_kern(width(b) - v)$;
   end;
  $free\_node(b, box\_node\_size)$; $b \leftarrow new\_glue(ss\_glue)$; $link(b) \leftarrow p$;
  while $link(p) \neq null$ **do** $p \leftarrow link(p)$;
  $link(p) \leftarrow new\_glue(ss\_glue)$; $rebox \leftarrow hpack(b, w, exactly)$;
  end
 else begin $width(b) \leftarrow w$; $rebox \leftarrow b$;
  end;
 end;

759.   Here is a subroutine that creates a new glue specification from another one that is expressed in 'mu', given the value of the math unit.

 define $mu\_mult(\texttt{\#}) \equiv nx\_plus\_y(n, \texttt{\#}, xn\_over\_d(\texttt{\#}, f, ´200000))$

function $math\_glue(g : pointer; m : scaled): pointer;$
 var p: $pointer$; { the new glue specification }
  n: $integer$; { integer part of m }
  f: $scaled$; { fraction part of m }
 begin $n \leftarrow x\_over\_n(m, ´200000)$; $f \leftarrow remainder$;
 if $f < 0$ **then**
  begin $decr(n)$; $f \leftarrow f + ´200000$;
  end;
 $p \leftarrow get\_node(glue\_spec\_size)$; $width(p) \leftarrow mu\_mult(width(g))$; { convert mu to pt }
 $stretch\_order(p) \leftarrow stretch\_order(g)$;
 if $stretch\_order(p) = normal$ **then** $stretch(p) \leftarrow mu\_mult(stretch(g))$
 else $stretch(p) \leftarrow stretch(g)$;
 $shrink\_order(p) \leftarrow shrink\_order(g)$;
 if $shrink\_order(p) = normal$ **then** $shrink(p) \leftarrow mu\_mult(shrink(g))$
 else $shrink(p) \leftarrow shrink(g)$;
 $math\_glue \leftarrow p$;
 end;

760.   The *math_kern* subroutine removes *mu_glue* from a kern node, given the value of the math unit.

procedure *math_kern*(p : *pointer*; m : *scaled*);
  var n: *integer*;   { integer part of m }
    f: *scaled*;   { fraction part of m }
  begin if *subtype*(p) = *mu_glue* **then**
    begin $n \leftarrow$ *x_over_n*(m, ´200000); $f \leftarrow$ *remainder*;
    if $f < 0$ **then**
      begin *decr*(n); $f \leftarrow f +$ ´200000;
      end;
    width(p) $\leftarrow$ *mu_mult*(*width*(p)); *subtype*(p) $\leftarrow$ *explicit*;
    end;
  end;

761.   Sometimes it is necessary to destroy an mlist. The following subroutine empties the current list, assuming that *abs*(*mode*) = *mmode*.

procedure *flush_math*;
  begin *flush_node_list*(*link*(*head*)); *flush_node_list*(*incompleat_noad*); *link*(*head*) $\leftarrow$ *null*; *tail* $\leftarrow$ *head*;
  incompleat_noad $\leftarrow$ *null*;
  end;

762. Typesetting math formulas. TEX's most important routine for dealing with formulas is called *mlist_to_hlist*. After a formula has been scanned and represented as an mlist, this routine converts it to an hlist that can be placed into a box or incorporated into the text of a paragraph. There are three implicit parameters, passed in global variables: *cur_mlist* points to the first node or noad in the given mlist (and it might be *null*); *cur_style* is a style code; and *mlist_penalties* is *true* if penalty nodes for potential line breaks are to be inserted into the resulting hlist. After *mlist_to_hlist* has acted, *link*(*temp_head*) points to the translated hlist.

Since mlists can be inside mlists, the procedure is recursive. And since this is not part of TEX's inner loop, the program has been written in a manner that stresses compactness over efficiency.

⟨ Global variables 13 ⟩ +≡
cur_mlist: *pointer*;   { beginning of mlist to be translated }
cur_style: *small_number*;   { style code at current place in the list }
cur_size: *integer*;   { size code corresponding to *cur_style* }
cur_mu: *scaled*;   { the math unit width corresponding to *cur_size* }
mlist_penalties: *boolean*;   { should *mlist_to_hlist* insert penalties? }

763. The recursion in *mlist_to_hlist* is due primarily to a subroutine called *clean_box* that puts a given noad field into a box using a given math style; *mlist_to_hlist* can call *clean_box*, which can call *mlist_to_hlist*.

The box returned by *clean_box* is "clean" in the sense that its *shift_amount* is zero.

procedure *mlist_to_hlist*; *forward*;
function *clean_box*(*p* : *pointer*; *s* : *small_number*): *pointer*;
  label *found*;
  var *q*: *pointer*;   { beginning of a list to be boxed }
    save_style: *small_number*;   { *cur_style* to be restored }
    x: *pointer*;   { box to be returned }
    r: *pointer*;   { temporary pointer }
  begin case *math_type*(*p*) **of**
  math_char: **begin** *cur_mlist* ← *new_noad*; *mem*[*nucleus*(*cur_mlist*)] ← *mem*[*p*];
    end;
  sub_box: **begin** *q* ← *info*(*p*); **goto** *found*;
    end;
  sub_mlist: *cur_mlist* ← *info*(*p*);
  othercases begin *q* ← *new_null_box*; **goto** *found*;
    end
  endcases;
  save_style ← *cur_style*; *cur_style* ← *s*; *mlist_penalties* ← *false*;
  mlist_to_hlist; *q* ← *link*(*temp_head*);   { recursive call }
  cur_style ← *save_style*;   { restore the style }
  ⟨ Set up the values of *cur_size* and *cur_mu*, based on *cur_style* 746 ⟩;
found: **if** *is_char_node*(*q*) ∨ (*q* = *null*) **then** *x* ← *hpack*(*q*, *natural*)
  else if (*link*(*q*) = *null*) ∧ (*type*(*q*) ≤ *vlist_node*) ∧ (*shift_amount*(*q*) = 0) **then** *x* ← *q*
        { it's already clean }
    else *x* ← *hpack*(*q*, *natural*);
  ⟨ Simplify a trivial box 764 ⟩;
  clean_box ← *x*;
  end;

764.   Here we save memory space in a common case.

⟨ Simplify a trivial box 764 ⟩ ≡
  $q \leftarrow list\_ptr(x)$;
  if $is\_char\_node(q)$ **then**
    begin $r \leftarrow link(q)$;
    if $r \neq null$ **then**
      if $link(r) = null$ **then**
        if $\neg is\_char\_node(r)$ **then**
          if $type(r) = kern\_node$ **then**   { unneeded italic correction }
            begin $free\_node(r, small\_node\_size)$; $link(q) \leftarrow null$;
            end;
    end

This code is used in section 763.

765.   It is convenient to have a procedure that converts a *math_char* field to an "unpacked" form. The *fetch* routine sets *cur_f*, *cur_c*, and *cur_i* to the font code, character code, and character information bytes of a given noad field. It also takes care of issuing error messages for nonexistent characters; in such cases, *char_exists*(*cur_i*) will be *false* after *fetch* has acted, and the field will also have been reset to *empty*.

procedure $fetch(a : pointer)$;   { unpack the *math_char* field a }
  begin $cur\_c \leftarrow cast\_to\_ushort(character(a))$; $cur\_f \leftarrow fam\_fnt(fam(a) + cur\_size)$;
  $cur\_c \leftarrow cur\_c + (plane\_and\_fam\_field(a)$ **div** ″100) ∗ ″10000;
  if $cur\_f = null\_font$ **then** ⟨ Complain about an undefined family and set *cur_i* null 766 ⟩
  else if $is\_native\_font(cur\_f)$ **then**
      begin $cur\_i \leftarrow null\_character$;
      end
    else begin if $(qo(cur\_c) \geq font\_bc[cur\_f]) \wedge (qo(cur\_c) \leq font\_ec[cur\_f])$ **then**
        $cur\_i \leftarrow char\_info(cur\_f)(cur\_c)$
      else $cur\_i \leftarrow null\_character$;
      if $\neg(char\_exists(cur\_i))$ **then**
        begin $char\_warning(cur\_f, qo(cur\_c))$; $math\_type(a) \leftarrow empty$; $cur\_i \leftarrow null\_character$;
        end;
      end;
  end;

766.   ⟨ Complain about an undefined family and set *cur_i* null 766 ⟩ ≡
  begin $print\_err("")$; $print\_size(cur\_size)$; $print\_char("␣")$; $print\_int(fam(a))$;
  $print("␣is␣undefined␣(character␣")$; $print\_ASCII(qo(cur\_c))$; $print\_char(")")$;
  $help4("Somewhere␣in␣the␣math␣formula␣just␣ended,␣you␣used␣the")$
  $("stated␣character␣from␣an␣undefined␣font␣family.␣For␣example,")$
  $("plain␣TeX␣doesn´t␣allow␣\it␣or␣\sl␣in␣subscripts.␣Proceed,")$
  $("and␣I´ll␣try␣to␣forget␣that␣I␣needed␣that␣character.")$; $error$; $cur\_i \leftarrow null\_character$;
  $math\_type(a) \leftarrow empty$;
  end

This code is used in section 765.

767.   The outputs of *fetch* are placed in global variables.

⟨ Global variables 13 ⟩ +≡
cur_f: $internal\_font\_number$;   { the *font* field of a *math_char* }
cur_c: $integer$;   { the *character* field of a *math_char* }
cur_i: $four\_quarters$;   { the *char_info* of a *math_char*, or a lig/kern instruction }

768.   We need to do a lot of different things, so *mlist_to_hlist* makes two passes over the given mlist.

The first pass does most of the processing: It removes "mu" spacing from glue, it recursively evaluates all subsidiary mlists so that only the top-level mlist remains to be handled, it puts fractions and square roots and such things into boxes, it attaches subscripts and superscripts, and it computes the overall height and depth of the top-level mlist so that the size of delimiters for a *left_noad* and a *right_noad* will be known. The hlist resulting from each noad is recorded in that noad's *new_hlist* field, an integer field that replaces the *nucleus* or *thickness*.

The second pass eliminates all noads and inserts the correct glue and penalties between nodes.

> **define** *new_hlist*(#) ≡ *mem*[*nucleus*(#)].*int*   { the translation of an mlist }

769.   Here is the overall plan of *mlist_to_hlist*, and the list of its local variables.

> **define** *done_with_noad* = 80   { go here when a noad has been fully translated }
> **define** *done_with_node* = 81   { go here when a node has been fully converted }
> **define** *check_dimensions* = 82   { go here to update *max_h* and *max_d* }
> **define** *delete_q* = 83   { go here to delete *q* and move to the next node }

⟨ Declare math construction procedures 777 ⟩

procedure *mlist_to_hlist*;

 label *reswitch*, *check_dimensions*, *done_with_noad*, *done_with_node*, *delete_q*, *done*;

 var *mlist*: *pointer*;   { beginning of the given list }

  penalties: *boolean*;   { should penalty nodes be inserted? }

  style: *small_number*;   { the given style }

  save_style: *small_number*;   { holds *cur_style* during recursion }

  q: *pointer*;   { runs through the mlist }

  r: *pointer*;   { the most recent noad preceding *q* }

  r_type: *small_number*;   { the *type* of noad *r*, or *op_noad* if *r* = *null* }

  t: *small_number*;   { the effective *type* of noad *q* during the second pass }

  p, x, y, z: *pointer*;   { temporary registers for list construction }

  pen: *integer*;   { a penalty to be inserted }

  s: *small_number*;   { the size of a noad to be deleted }

  max_h, *max_d*: *scaled*;   { maximum height and depth of the list translated so far }

  delta: *scaled*;   { offset between subscript and superscript }

 begin *mlist* ← *cur_mlist*; *penalties* ← *mlist_penalties*; *style* ← *cur_style*;

  { tuck global parameters away as local variables }

 q ← *mlist*; *r* ← *null*; *r_type* ← *op_noad*; *max_h* ← 0; *max_d* ← 0;

 ⟨ Set up the values of *cur_size* and *cur_mu*, based on *cur_style* 746 ⟩;

 while *q* ≠ *null* **do** ⟨ Process node-or-noad *q* as much as possible in preparation for the second pass of
  mlist_to_hlist, then move to the next item in the mlist 770 ⟩;

 ⟨ Convert a final *bin_noad* to an *ord_noad* 772 ⟩;

 ⟨ Make a second pass over the mlist, removing all noads and inserting the proper spacing and
  penalties 808 ⟩;

 end;

770.   We use the fact that no character nodes appear in an mlist, hence the field $type(q)$ is always present.

⟨ Process node-or-noad q as much as possible in preparation for the second pass of $mlist\_to\_hlist$, then move
        to the next item in the mlist 770 ⟩ ≡
  begin ⟨ Do first-pass processing based on $type(q)$; **goto** $done\_with\_noad$ if a noad has been fully

vcenter_noad: *make_vcenter*(q);

This code is used in section 771.

777. Most of the actual construction work of *mlist_to_hlist* is done by procedures with names like *make_fraction*, *make_radical*, etc. To illustrate the general setup of such procedures, let's begin with a couple of simple ones.

⟨ Declare math construction procedures 777 ⟩ ≡
procedure *make_over*(q : *pointer*);
 begin $info(nucleus(q)) \leftarrow overbar(clean\_box(nucleus(q), cramped\_style(cur\_style)),$
  $3 * default\_rule\_thickness, default\_rule\_thickness)$; $math\_type(nucleus(q)) \leftarrow sub\_box$;
 end;

See also sections 778, 779, 780, 781, 787, 793, 796, 800, and 810.

This code is used in section 769.

778. ⟨Declare math construction procedures 777⟩ +≡

procedure *make_under*(*q* : *pointer*);

  var *p, x, y*: *pointer*; { temporary registers for box construction }

    delta: *scaled*; { overall height plus depth }

  begin *x* ← *clean_box*(*nucleus*(*q*), *cur_style*); *p* ← *new_kern*(3 ∗ *default_rule_thickness*); *link*(*x*) ← *p*;

  link(*p*) ← *fraction_rule*(*default_rule_thickness*); *y* ← *vpack*(*x*, *natural*);

  delta ← *height*(*y*) + *depth*(*y*) + *default_rule_thickness*; *height*(*y*) ← *height*(*x*);

  depth(*y*) ← *delta* − *height*(*y*); *info*(*nucleus*(*q*)) ← *y*; *math_type*(*nucleus*(*q*)) ← *sub_box*;

  end;

779. ⟨Declare math construction procedures 777⟩ +≡

procedure *make_vcenter*(*q* : *pointer*);

  var *v*: *pointer*; { the box that should be centered vertically }

    delta: *scaled*; { its height plus depth }

  begin *v* ← *info*(*nucleus*(*q*));

  if *type*(*v*) ≠ *vlist_node* **then** *confusion*("vcenter");

  delta ← *height*(*v*) + *depth*(*v*); *height*(*v*) ← *axis_height*(*cur_size*) + *half*(*delta*);

  depth(*v*) ← *delta* − *height*(*v*);

  end;

780. According to the rules in the `DVI` file specifications, we ensure alignment between a square root sign and the rule above its nucleus by assuming that the baseline of the square-root symbol is the same as the bottom of the rule. The height of the square-root symbol will be the thickness of the rule, and the depth of the square-root symbol should exceed or equal the height-plus-depth of the nucleus plus a certain minimum clearance clr. The symbol will be placed so that the actual clearance is clr plus half the excess.

⟨ Declare math construction procedures 777 ⟩ +≡

    new_hlist(*q*) ← *hpack*(*x*, *natural*)

This code is used in section 787.

793.   If the nucleus of an *op_noad* is a single character, it is to be centered vertically with respect to the axis, after first being enlarged (via a character list in the font) if we are in display style. The normal convention for placing displayed limits is to put them above and below the operator in display style.

The italic correction is removed from the character if there is a subscript and the limits are not being displayed. The *make_op* routine returns the value that should be used as an offset between subscript and superscript.

After *make_op* has acted, *subtype*(*q*) will be *limits* if and only if the limits have been set above and below the operator. In that case, *new_hlist*(*q*) will already contain the desired final box.

⟨Declare math construction procedures 777⟩ +≡

    end;
  othercases $confusion("mlist3")$
  endcases

This code is used in section 808.

810.   The $make\_left\_right$ function constructs a left or right delimiter of the required size and returns the value $open\_noad$ or $close\_noad$. The $right\_noad$ and $left\_noad$ will both be based on the original $style$, so they will have consistent sizes.

  We use the fact that $right\_noad - left\_noad = close\_noad - open\_noad$.

⟨Declare math construction procedures 777⟩ +≡
function $make\_left\_right(q : pointer; style : small\_number; max\_d, max\_h : scaled): small\_number$;
  var $delta, delta1, delta2: scaled$;   {dimensions used in the calculation}
  begin $cur\_style \leftarrow style$; ⟨Set up the values of cur_size and cur_mu, based on cur_style 746⟩;
  $delta2 \leftarrow max\_d + axis\_height(cur\_size)$; $delta1 \leftarrow max\_h + max\_d - delta2$;
  if $delta2 > delta1$ **then** $delta1 \leftarrow delta2$;   {$delta1$ is max distance from axis}
  $delta \leftarrow (delta1 \textbf{ div } 500) * delimiter\_factor$; $delta2 \leftarrow delta1 + delta1 - delimiter\_shortfall$;
  if $delta < delta2$ **then** $delta \leftarrow delta2$;
  $new\_hlist(q) \leftarrow var\_delimiter(delimiter(q), cur\_size, delta)$;
  $make\_left\_right \leftarrow type(q) - (left\_noad - open\_noad)$;   {$open\_noad$ or $close\_noad$}
  end;

811.   ⟨Change the current style and **goto** $delete\_q$ 811⟩ ≡
  begin $cur\_style \leftarrow subtype(q)$; $s \leftarrow style\_node\_size$;
  ⟨Set up the values of cur_size and cur_mu, based on cur_style 746⟩;
  goto $delete\_q$;
  end

This code is used in section 809.

812. The inter-element spacing in math formulas depends on an 8×8 table that TEX preloads as a 64-digit string. The elements of this string have the following significance:

> 0 means no space;
>
> 1 means a conditional thin space (`\nonscript\mskip\thinmuskip`);
>
> 2 means a thin space (`\mskip\thinmuskip`);
>
> 3 means a conditional medium space (`\nonscript\mskip\medmuskip`);
>
> 4 means a conditional thick space (`\nonscript\mskip\thickmuskip`);
>
> * means an impossible case.

This is all pretty cryptic, but *The TEXbook* explains what is supposed to happen, and the string makes it happen.

A global variable *magic_offset* is computed so that if a and b are in the range *ord_noad* .. *inner_noad*, then *str_pool*$[a * 8 + b + magic\_offset]$ is the digit for spacing between noad types a and b.

If Pascal had provided a good way to preload constant arrays, this part of the program would not have been so strange.

define *math_spacing* =
  "0234000122*4000133**3**344*0400400*000000234000111*1111112341011"

⟨ Global variables 13 ⟩ +≡
magic_offset: *integer*;   { used to find inter-element spacing }

813.   ⟨ Compute the magic offset 813 ⟩ ≡
  magic_offset ← *str_start_macro*(*math_spacing*) − 9 ∗ *ord_noad*
This code is used in section 1391.

814.   ⟨ Append inter-element spacing based on *r_type* and *t* 814 ⟩ ≡
  if *r_type* > 0 **then**   { not the first noad }
    begin case *so*(*str_pool*[*r_type* ∗ 8 + *t* + *magic_offset*]) **of**
    "0": *x* ← 0;
    "1": **if** *cur_style* < *script_style* **then** *x* ← *thin_mu_skip_code* **else** *x* ← 0;
    "2": *x* ← *thin_mu_skip_code*;
    "3": **if** *cur_style* < *script_style* **then** *x* ← *med_mu_skip_code* **else** *x* ← 0;
    "4": **if** *cur_style* < *script_style* **then** *x* ← *thick_mu_skip_code* **else** *x* ← 0;
    othercases *confusion*("mlist4")
    endcases;
    if *x* ≠ 0 **then**
      begin *y* ← *math_glue*(*glue_par*(*x*), *cur_mu*); *z* ← *new_glue*(*y*); *glue_ref_count*(*y*) ← *null*;
      link(*p*) ← *z*; *p* ← *z*;
      subtype(*z*) ← *x* + 1;   { store a symbolic subtype }
      end;
    end
This code is used in section 808.

815.   We insert a penalty node after the hlist entries of noad q if *pen* is not an "infinite" penalty, and if the node immediately following q is not a penalty node or a *rel_noad* or absent entirely.

⟨ Append any *new_hlist* entries for q, and any appropriate penalties 815 ⟩ ≡
  if *new_hlist*$(q) \neq null$ **then**
    begin *link*$(p) \leftarrow$ *new_hlist*(q);
    repeat $p \leftarrow$ *link*(p);
    until *link*$(p) = null$;
    end;
  if *penalties* **then**
    if *link*$(q) \neq null$ **then**
      if *pen* < *inf_penalty* **then**
        begin *r_type* $\leftarrow$ *type*$(link(q))$;
        if *r_type* $\neq$ *penalty_node* **then**
          if *r_type* $\neq$ *rel_noad* **then**
            begin $z \leftarrow$ *new_penalty*(pen); *link*$(p) \leftarrow z$; $p \leftarrow z$;
            end;
        end

This code is used in section 808.

816.   Alignment.   It's sort of a miracle whenever \halign and \valign work, because they cut across so many of the control structures of TEX.

Therefore the present page is probably not the best place for a beginner to start reading this program; it is better to master everything else first.

Let us focus our thoughts on an example of what the input might be, in order to get some idea about how the alignment miracle happens. The example doesn't do anything useful, but it is sufficiently general to indicate all of the special cases that must be dealt with; please do not be disturbed by its apparent complexity and meaninglessness.

```
\tabskip 2pt plus 3pt
\halign to 300pt{u1#v1&
        \tabskip 1pt plus 1fil u2#v2&
        u3#v3\cr
    a1&\omit a2&\vrule\cr
    \noalign{\vskip 3pt}
    b1\span b2\cr
    \omit&c2\span\omit\cr}
```

Here's what happens:

(0) When '\halign to 300pt{' is scanned, the *scan_spec* routine places the 300pt dimension onto the *save_stack*, and an *align_group* code is placed above it. This will make it possible to complete the alignment when the matching '}' is found.

(1) The preamble is scanned next. Macros in the preamble are not expanded, except as part of a tabskip specification. For example, if u2 had been a macro in the preamble above, it would have been expanded, since TEX must look for 'minus...' as part of the tabskip glue. A "preamble list" is constructed based on the user's preamble; in our case it contains the following seven items:

\glue 2pt plus 3pt	(the tabskip preceding column 1)
\alignrecord, width $-\infty$	(preamble info for column 1)
\glue 2pt plus 3pt	(the tabskip between columns 1 and 2)
\alignrecord, width $-\infty$	(preamble info for column 2)
\glue 1pt plus 1fil	(the tabskip between columns 2 and 3)
\alignrecord, width $-\infty$	(preamble info for column 3)
\glue 1pt plus 1fil	(the tabskip following column 3)

These "alignrecord" entries have the same size as an *unset_node*, since they will later be converted into such nodes. However, at the moment they have no *type* or *subtype* fields; they have *info* fields instead, and these *info* fields are initially set to the value *end_span*, for reasons explained below. Furthermore, the alignrecord nodes have no *height* or *depth* fields; these are renamed *u_part* and *v_part*, and they point to token lists for the templates of the alignment. For example, the *u_part* field in the first alignrecord points to the token list 'u1', i.e., the template preceding the '#' for column 1.

(2) TEX now looks at what follows the \cr that ended the preamble. It is not '\noalign' or '\omit', so this input is put back to be read again, and the template 'u1' is fed to the scanner. Just before reading 'u1', TEX goes into restricted horizontal mode. Just after reading 'u1', TEX will see 'a1', and then (when the & is sensed) TEX will see 'v1'. Then TEX scans an *endv* token, indicating the end of a column. At this point an *unset_node* is created, containing the contents of the current hlist (i.e., 'u1a1v1'). The natural width of this unset node replaces the *width* field of the alignrecord for column 1; in general, the alignrecords will record the maximum natural width that has occurred so far in a given column.

(3) Since '\omit' follows the '&', the templates for column 2 are now bypassed. Again TEX goes into restricted horizontal mode and makes an *unset_node* from the resulting hlist; but this time the hlist contains simply 'a2'. The natural width of the new unset box is remembered in the *width* field of the alignrecord for column 2.

(4) A third *unset_node* is created for column 3, using essentially the mechanism that worked for column 1; this unset box contains 'u3\vrule v3'. The vertical rule in this case has running dimensions that will later

extend to the height and depth of the whole first row, since each *unset_node* in a row will eventually inherit the height and depth of its enclosing box.

(5) The first row has now ended; it is made into a single unset box comprising the following seven items:

```
\glue 2pt plus 3pt
\unsetbox for 1 column: u1a1v1
\glue 2pt plus 3pt
\unsetbox for 1 column: a2
\glue 1pt plus 1fil
\unsetbox for 1 column: u3\vrule v3
\glue 1pt plus 1fil
```

The width of this unset row is unimportant, but it has the correct height and depth, so the correct baselineskip glue will be computed as the row is inserted into a vertical list.

(6) Since '\noalign' follows the current \cr, TEX appends additional material (in this case \vskip 3pt) to the vertical list. While processing this material, TEX will be in internal vertical mode, and *no_align_group* will be on *save_stack*.

(7) The next row produces an unset box that looks like this:

```
\glue 2pt plus 3pt
\unsetbox for 2 columns: u1b1v1u2b2v2
\glue 1pt plus 1fil
\unsetbox for 1 column: (empty)
\glue 1pt plus 1fil
```

The natural width of the unset box that spans columns 1 and 2 is stored in a "span node," which we will explain later; the *info* field of the alignrecord for column 1 now points to the new span node, and the *info* of the span node points to *end_span*.

(8) The final row produces the unset box

```
\glue 2pt plus 3pt
\unsetbox for 1 column: (empty)
\glue 2pt plus 3pt
\unsetbox for 2 columns: u2c2v2
\glue 1pt plus 1fil
```

A new span node is attached to the alignrecord for column 2.

(9) The last step is to compute the true column widths and to change all the unset boxes to hboxes, appending the whole works to the vertical list that encloses the \halign. The rules for deciding on the final widths of each unset column box will be explained below.

Note that as \halign is being processed, we fearlessly give up control to the rest of TEX. At critical junctures, an alignment routine is called upon to step in and do some little action, but most of the time these routines just lurk in the background. It's something like post-hypnotic suggestion.

817.   We have mentioned that alignrecords contain no *height* or *depth* fields. Their *glue_sign* and *glue_order* are pre-empted as well, since it is necessary to store information about what to do when a template ends. This information is called the *extra_info* field.

define $u\_part(\#) \equiv mem[\# + height\_offset].int$ { pointer to $\langle u_j \rangle$ token list }
define $v\_part(\#) \equiv mem[\# + depth\_offset].int$ { pointer to $\langle v_j \rangle$ token list }
define $extra\_info(\#) \equiv info(\# + list\_offset)$ { info to remember during template }

818.   Alignments can occur within alignments, so a small stack is used to access the alignrecord information. At each level we have a *preamble* pointer, indicating the beginning of the preamble list; a *cur_align* pointer, indicating the current position in the preamble list; a *cur_span* pointer, indicating the value of *cur_align* at the beginning of a sequence of spanned columns; a *cur_loop* pointer, indicating the tabskip glue before an alignrecord that should be copied next if the current list is extended; and the *align_state* variable, which indicates the nesting of braces so that \cr and \span and tab marks are properly intercepted. There also are pointers *cur_head* and *cur_tail* to the head and tail of a list of adjustments being moved out from horizontal mode to vertical mode.

The current values of these seven quantities appear in global variables; when they have to be pushed down, they are stored in 5-word nodes, and *align_ptr* points to the topmost such node.

> **define** *preamble* ≡ *link*(*align_head*)   { the current preamble list }
> **define** *align_stack_node_size* = 6   { number of *mem* words to save alignment states }

⟨ Global variables 13 ⟩ +≡
cur_align: *pointer*;   { current position in preamble list }
cur_span: *pointer*;   { start of currently spanned columns in preamble list }
cur_loop: *pointer*;   { place to copy when extending a periodic preamble }
align_ptr: *pointer*;   { most recently pushed-down alignment stack node }
cur_head, *cur_tail*: *pointer*;   { adjustment list pointers }
cur_pre_head, *cur_pre_tail*: *pointer*;   { pre-adjustment list pointers }

819.   The *align_state* and *preamble* variables are initialized elsewhere.

⟨ Set initial values of key variables 23 ⟩ +≡
  align_ptr ← *null*; *cur_align* ← *null*; *cur_span* ← *null*; *cur_loop* ← *null*; *cur_head* ← *null*;
  cur_tail ← *null*; *cur_pre_head* ← *null*; *cur_pre_tail* ← *null*;

820.   Alignment stack maintenance is handled by a pair of trivial routines called *push_alignment* and *pop_alignment*.

procedure *push_alignment*;
  var *p*: *pointer*;   { the new alignment stack node }
  begin *p* ← *get_node*(*align_stack_node_size*); *link*(*p*) ← *align_ptr*; *info*(*p*) ← *cur_align*;
  llink(*p*) ← *preamble*; *rlink*(*p*) ← *cur_span*; *mem*[*p* + 2].*int* ← *cur_loop*; *mem*[*p* + 3].*int* ← *align_state*;
  info(*p* + 4) ← *cur_head*; *link*(*p* + 4) ← *cur_tail*; *info*(*p* + 5) ← *cur_pre_head*; *link*(*p* + 5) ← *cur_pre_tail*;
  align_ptr ← *p*; *cur_head* ← *get_avail*; *cur_pre_head* ← *get_avail*;
  end;

procedure *pop_alignment*;
  var *p*: *pointer*;   { the top alignment stack node }
  begin *free_avail*(*cur_head*); *free_avail*(*cur_pre_head*); *p* ← *align_ptr*; *cur_tail* ← *link*(*p* + 4);
  cur_head ← *info*(*p* + 4); *cur_pre_tail* ← *link*(*p* + 5); *cur_pre_head* ← *info*(*p* + 5);
  align_state ← *mem*[*p* + 3].*int*; *cur_loop* ← *mem*[*p* + 2].*int*; *cur_span* ← *rlink*(*p*); *preamble* ← *llink*(*p*);
  cur_align ← *info*(*p*); *align_ptr* ← *link*(*p*); *free_node*(*p*, *align_stack_node_size*);
  end;

821.   TEX has eight procedures that govern alignments: *init_align* and *fin_align* are used at the very beginning and the very end; *init_row* and *fin_row* are used at the beginning and end of individual rows; *init_span* is used at the beginning of a sequence of spanned columns (possibly involving only one column); *init_col* and *fin_col* are used at the beginning and end of individual columns; and *align_peek* is used after \cr to see whether the next item is \noalign.

We shall consider these routines in the order they are first used during the course of a complete \halign, namely *init_align*, *align_peek*, *init_row*, *init_span*, *init_col*, *fin_col*, *fin_row*, *fin_align*.

822.   When \halign or \valign has been scanned in an appropriate mode, T$_{\textrm{E}}$X calls *init_align*, whose task is to get everything off to a good start. This mostly involves scanning the preamble and putting its information into the preamble list.

⟨ Declare the procedure called *get_preamble_token* 830 ⟩
procedure *align_peek*; *forward*;
procedure *normal_paragraph*; *forward*;
procedure *init_align*;
   label *done*, *done1*, *done2*, *continue*;
   var *save_cs_ptr*: *pointer*;   { *warning_index* value for error messages }
     p: *pointer*;   { for short-term temporary use }
   begin *save_cs_ptr* ← *cur_cs*;   { \halign or \valign, usually }
   push_alignment; *align_state* ← −1000000;   { enter a new alignment level }
   ⟨ Check for improper alignment in displayed math 824 ⟩;
   push_nest;   { enter a new semantic level }
   ⟨ Change current mode to −*vmode* for \halign, −*hmode* for \valign 823 ⟩;
   scan_spec(*align_group*, *false*);
   ⟨ Scan the preamble and record it in the *preamble* list 825 ⟩;
   new_save_level(*align_group*);
   if *every_cr* ≠ *null* **then** *begin_token_list*(*every_cr*, *every_cr_text*);
   align_peek;   { look for \noalign or \omit }
   end;

823.   In vertical modes, *prev_depth* already has the correct value. But if we are in *mmode* (displayed formula mode), we reach out to the enclosing vertical mode for the *prev_depth* value that produces the correct baseline calculations.

⟨ Change current mode to −*vmode* for \halign, −*hmode* for \valign 823 ⟩ ≡
   if *mode* = *mmode* **then**
     begin *mode* ← −*vmode*; *prev_depth* ← *nest*[*nest_ptr* − 2].*aux_field*.*sc*;
     end
   else if *mode* > 0 **then** *negate*(*mode*)
This code is used in section 822.

824.   When \halign is used as a displayed formula, there should be no other pieces of mlists present.

⟨ Check for improper alignment in displayed math 824 ⟩ ≡
   if (*mode* = *mmode*) ∧ ((*tail* ≠ *head*) ∨ (*incompleat_noad* ≠ *null*)) **then**
     begin *print_err*("Improper␣"); *print_esc*("halign"); *print*("␣inside␣$$´s");
     help3("Displays␣can␣use␣special␣alignments␣(like␣\eqalignno)")
     ("only␣if␣nothing␣but␣the␣alignment␣itself␣is␣between␣$$´s.")
     ("So␣I´ve␣deleted␣the␣formulas␣that␣preceded␣this␣alignment."); *error*; *flush_math*;
     end
This code is used in section 822.

825. ⟨Scan the preamble and record it in the *preamble* list 825⟩ ≡
  preamble ← *null*; *cur_align* ← *align_head*; *cur_loop* ← *null*; *scanner_status* ← *aligning*;
  warning_index ← *save_cs_ptr*; *align_state* ← −1000000; { at this point, *cur_cmd* = *left_brace* }
  loop begin ⟨Append the current tabskip glue to the preamble list 826⟩;
    if *cur_cmd* = *car_ret* **then goto** *done*; { \cr ends the preamble }
    ⟨Scan preamble text until *cur_cmd* is *tab_mark* or *car_ret*, looking for changes in the tabskip glue;
       append an alignrecord to the preamble list 827⟩;
    end;
done: *scanner_status* ← *normal*

This code is used in section 822.

826. ⟨Append the current tabskip glue to the preamble list 826⟩ ≡
  link(*cur_align*) ← *new_param_glue*(*tab_skip_code*); *cur_align* ← *link*(*cur_align*)

This code is used in section 825.

827. ⟨Scan preamble text until *cur_cmd* is *tab_mark* or *car_ret*, looking for changes in the tabskip glue;
    append an alignrecord to the preamble list 827⟩ ≡
  ⟨Scan the template ⟨u_j⟩, putting the resulting token list in *hold_head* 831⟩;
  link(*cur_align*) ← *new_null_box*; *cur_align* ← *link*(*cur_align*); { a new alignrecord }
  info(*cur_align*) ← *end_span*; *width*(*cur_align*) ← *null_flag*; *u_part*(*cur_align*) ← *link*(*hold_head*);
  ⟨Scan the template ⟨v_j⟩, putting the resulting token list in *hold_head* 832⟩;
  v_part(*cur_align*) ← *link*(*hold_head*)

This code is used in section 825.

828. We enter '\span' into *eqtb* with *tab_mark* as its command code, and with *span_code* as the command modifier. This makes TEX interpret it essentially the same as an alignment delimiter like '&', yet it is recognizably different when we need to distinguish it from a normal delimiter. It also turns out to be useful to give a special *cr_code* to '\cr', and an even larger *cr_cr_code* to '\crcr'.

The end of a template is represented by two "frozen" control sequences called \endtemplate. The first has the command code *end_template*, which is > *outer_call*, so it will not easily disappear in the presence of errors. The *get_x_token* routine converts the first into the second, which has *endv* as its command code.

  define *span_code* = *special_char*   { distinct from any character }
  define *cr_code* = *span_code* + 1   { distinct from *span_code* and from any character }
  define *cr_cr_code* = *cr_code* + 1   { this distinguishes \crcr from \cr }
  define *end_template_token* ≡ *cs_token_flag* + *frozen_end_template*

⟨Put each of TEX's primitives into the hash table 252⟩ +≡
  primitive("span", *tab_mark*, *span_code*);
  primitive("cr", *car_ret*, *cr_code*); *text*(*frozen_cr*) ← "cr"; *eqtb*[*frozen_cr*] ← *eqtb*[*cur_val*];
  primitive("crcr", *car_ret*, *cr_cr_code*); *text*(*frozen_end_template*) ← "endtemplate";
  text(*frozen_endv*) ← "endtemplate"; *eq_type*(*frozen_endv*) ← *endv*; *equiv*(*frozen_endv*) ← *null_list*;
  eq_level(*frozen_endv*) ← *level_one*;
  eqtb[*frozen_end_template*] ← *eqtb*[*frozen_endv*]; *eq_type*(*frozen_end_template*) ← *end_template*;

829. ⟨Cases of *print_cmd_chr* for symbolic printing of primitives 253⟩ +≡
tab_mark: **if** *chr_code* = *span_code* **then** *print_esc*("span")
  else *chr_cmd*("alignment␣tab␣character␣");
car_ret: **if** *chr_code* = *cr_code* **then** *print_esc*("cr")
  else *print_esc*("crcr");

830. The preamble is copied directly, except that \tabskip causes a change to the tabskip glue, thereby possibly expanding macros that immediately follow it. An appearance of \span also causes such an expansion.

Note that if the preamble contains '\global\tabskip', the '\global' token survives in the preamble and the '\tabskip' defines new tabskip glue (locally).

⟨Declare the procedure called *get_preamble_token* 830⟩ ≡
procedure *get_preamble_token*;
  label *restart*;
  begin *restart*: *get_token*;
  while (*cur_chr* = *span_code*) ∧ (*cur_cmd* = *tab_mark*) **do**
    begin *get_token*; { this token will be expanded once }
    if *cur_cmd* > *max_command* **then**
      begin *expand*; *get_token*;
      end;
    end;
  if *cur_cmd* = *endv* **then** *fatal_error*("(interwoven␣alignment␣preambles␣are␣not␣allowed)");
  if (*cur_cmd* = *assign_glue*) ∧ (*cur_chr* = *glue_base* + *tab_skip_code*) **then**
    begin *scan_optional_equals*; *scan_glue*(*glue_val*);
    if *global_defs* > 0 **then** *geq_define*(*glue_base* + *tab_skip_code*, *glue_ref*, *cur_val*)
    else *eq_define*(*glue_base* + *tab_skip_code*, *glue_ref*, *cur_val*);
    goto *restart*;
    end;
  end;

This code is used in section 822.

831. Spaces are eliminated from the beginning of a template.

⟨Scan the template ⟨u_j⟩, putting the resulting token list in *hold_head* 831⟩ ≡
  p ← *hold_head*; *link*(*p*) ← *null*;
  loop begin *get_preamble_token*;
    if *cur_cmd* = *mac_param* **then goto** *done1*;
    if (*cur_cmd* ≤ *car_ret*) ∧ (*cur_cmd* ≥ *tab_mark*) ∧ (*align_state* = −1000000) **then**
      if (*p* = *hold_head*) ∧ (*cur_loop* = *null*) ∧ (*cur_cmd* = *tab_mark*) **then** *cur_loop* ← *cur_align*
      else begin *print_err*("Missing␣#␣inserted␣in␣alignment␣preamble");
        help3("There␣should␣be␣exactly␣one␣#␣between␣&´s,␣when␣an")
        ("\halign␣or␣\valign␣is␣being␣set␣up.␣In␣this␣case␣you␣had")
        ("none,␣so␣I´ve␣put␣one␣in;␣maybe␣that␣will␣work."); *back_error*; **goto** *done1*;
        end
    else if (*cur_cmd* ≠ *spacer*) ∨ (*p* ≠ *hold_head*) **then**
        begin *link*(*p*) ← *get_avail*; *p* ← *link*(*p*); *info*(*p*) ← *cur_tok*;
        end;
    end;
done1:

This code is used in section 827.

832. ⟨Scan the template ⟨v_j⟩, putting the resulting token list in *hold_head* 832⟩ ≡
  $p \leftarrow hold\_head$; $link(p) \leftarrow null$;
  loop begin *continue*: *get_preamble_token*;
    if $(cur\_cmd \leq car\_ret) \wedge (cur\_cmd \geq tab\_mark) \wedge (align\_state = -1000000)$ **then goto** *done2*;
    if $cur\_cmd = mac\_param$ **then**
        begin *print_err*("Only␣one␣#␣is␣allowed␣per␣tab");
        help3("There␣should␣be␣exactly␣one␣#␣between␣&´s,␣when␣an")
        ("\halign␣or␣\valign␣is␣being␣set␣up.␣In␣this␣case␣you␣had")
        ("more␣than␣one,␣so␣I´m␣ignoring␣all␣but␣the␣first."); *error*; **goto** *continue*;
        end;
    $link(p) \leftarrow get\_avail$; $p \leftarrow link(p)$; $info(p) \leftarrow cur\_tok$;
    end;
done2: $link(p) \leftarrow get\_avail$; $p \leftarrow link(p)$; $info(p) \leftarrow end\_template\_token$ { put \endtemplate at the end }
This code is used in section 827.

833. The tricky part about alignments is getting the templates into the scanner at the right time, and recovering control when a row or column is finished.

  We usually begin a row after each \cr has been sensed, unless that \cr is followed by \noalign or by the right brace that terminates the alignment. The *align_peek* routine is used to look ahead and do the right thing; it either gets a new row started, or gets a \noalign started, or finishes off the alignment.

⟨Declare the procedure called *align_peek* 833⟩ ≡
procedure *align_peek*;
  label *restart*;
  begin *restart*: $align\_state \leftarrow 1000000$;
  repeat *get_x_or_protected*;
  until $cur\_cmd \neq spacer$;
  if $cur\_cmd = no\_align$ **then**
    begin *scan_left_brace*; *new_save_level*(*no_align_group*);
    if $mode = -vmode$ **then** *normal_paragraph*;
    end
  else if $cur\_cmd = right\_brace$ **then** *fin_align*
    else if $(cur\_cmd = car\_ret) \wedge (cur\_chr = cr\_cr\_code)$ **then goto** *restart*   { ignore \crcr }
      else begin *init_row*;   { start a new row }
        init_col;   { start a new column and replace what we peeked at }
        end;
  end;
This code is used in section 848.

834. To start a row (i.e., a 'row' that rhymes with 'dough' but not with 'bough'), we enter a new semantic level, copy the first tabskip glue, and change from internal vertical mode to restricted horizontal mode or vice versa. The *space_factor* and *prev_depth* are not used on this semantic level, but we clear them to zero just to be tidy.

⟨Declare the procedure called *init_span* 835⟩
procedure *init_row*;
  begin *push_nest*; $mode \leftarrow (-hmode - vmode) - mode$;
  if $mode = -hmode$ **then** $space\_factor \leftarrow 0$ **else** $prev\_depth \leftarrow 0$;
  tail_append(*new_glue*(*glue_ptr*(*preamble*))); $subtype(tail) \leftarrow tab\_skip\_code + 1$;
  $cur\_align \leftarrow link(preamble)$; $cur\_tail \leftarrow cur\_head$; $cur\_pre\_tail \leftarrow cur\_pre\_head$; *init_span*(*cur_align*);
  end;

835.   The parameter to *init_span* is a pointer to the alignrecord where the next column or group of columns will begin. A new semantic level is entered, so that the columns will generate a list for subsequent packaging.

⟨ Declare the procedure called *init_span* 835 ⟩ ≡

procedure *init_span*(*p* : *pointer*);
   begin *push_nest*;
   if *mode* = −*hmode* **then** *space_factor* ← 1000
   else begin *prev_depth* ← *ignore_depth*; *normal_paragraph*;
      end;
   cur_span ← *p*;
   end;

This code is used in section 834.

836.   When a column begins, we assume that *cur_cmd* is either *omit* or else the current token should be put back into the input until the ⟨*u$_j$*⟩ template has been scanned. (Note that *cur_cmd* might be *tab_mark* or *car_ret*.) We also assume that *align_state* is approximately 1000000 at this time. We remain in the same mode, and start the template if it is called for.

procedure *init_col*;
   begin *extra_info*(*cur_align*) ← *cur_cmd*;
   if *cur_cmd* = *omit* **then** *align_state* ← 0
   else begin *back_input*; *begin_token_list*(*u_part*(*cur_align*), *u_template*);
      end; { now *align_state* = 1000000 }
   end;

837.   The scanner sets *align_state* to zero when the ⟨*u$_j$*⟩ template ends. When a subsequent \cr or \span or tab mark occurs with *align_state* = 0, the scanner activates the following code, which fires up the ⟨*v$_j$*⟩ template. We need to remember the *cur_chr*, which is either *cr_cr_code*, *cr_code*, *span_code*, or a character code, depending on how the column text has ended.

   This part of the program had better not be activated when the preamble to another alignment is being scanned, or when no alignment preamble is active.

⟨ Insert the ⟨*v$_j$*⟩ template and **goto** *restart* 837 ⟩ ≡

   begin if (*scanner_status* = *aligning*) ∨ (*cur_align* = *null*) **then**
      fatal_error("(interwoven␣alignment␣preambles␣are␣not␣allowed)");
   cur_cmd ← *extra_info*(*cur_align*); *extra_info*(*cur_align*) ← *cur_chr*;
   if *cur_cmd* = *omit* **then** *begin_token_list*(*omit_template*, *v_template*)
   else *begin_token_list*(*v_part*(*cur_align*), *v_template*);
   align_state ← 1000000; **goto** *restart*;
   end

This code is used in section 372.

838.   The token list *omit_template* just referred to is a constant token list that contains the special control sequence \endtemplate only.

⟨ Initialize the special list heads and constant nodes 838 ⟩ ≡

   info(*omit_template*) ← *end_template_token*;   { *link*(*omit_template*) = *null* }

See also sections 845, 868, 1035, and 1042.

This code is used in section 189.

839.   When the *endv* command at the end of a $\langle v_j \rangle$ template comes through the scanner, things really start to happen; and it is the *fin_col* routine that makes them happen. This routine returns *true* if a row as well as a column has been finished.

function *fin_col*: *boolean*;
  label *exit*;
  var *p*: *pointer*;   { the alignrecord after the current one }

  ⟨Determine the shrink order 707⟩;
  $glue\_sign(u) \leftarrow o;\ glue\_shrink(u) \leftarrow total\_shrink[o];$
  $pop\_nest;\ link(tail) \leftarrow u;\ tail \leftarrow u;$
  end
This code is used in section 839.

845. A span node is a 2-word record containing *width*, *info*, and *link* fields. The *link* field is not really a link, it indicates the number of spanned columns; the *info* field points to a span node for the same starting column, having a greater extent of spanning, or to *end_span*, which has the largest possible *link* field; the *width* field holds the largest natural width corresponding to a particular set of spanned columns.

  A list of the maximum widths so far, for spanned columns starting at a given column, begins with the *info* field of the alignrecord for that column.

  define $span\_node\_size = 2$ { number of *mem* words for a span node }

⟨Initialize the special list heads and constant nodes 838⟩ +≡
  $link(end\_span) \leftarrow max\_quarterword + 1;\ info(end\_span) \leftarrow null;$

846. ⟨Update width entry for spanned columns 846⟩ ≡
  begin $q \leftarrow cur\_span$;
  repeat $incr(n)$; $q \leftarrow link(link(q))$;
  until $q = cur\_align$;
  if $n > max\_quarterword$ **then** $confusion($"too␣many␣spans"$)$;   {this can happen, but won't}
  $q \leftarrow cur\_span$;
  while $link(info(q)) < n$ **do** $q \leftarrow info(q)$;
  if $link(info(q)) > n$ **then**
    begin $s \leftarrow get\_node(span\_node\_size)$; $info(s) \leftarrow info(q)$; $link(s) \leftarrow n$; $info(q) \leftarrow s$; $width(s) \leftarrow w$;
    end
  else if $width(info(q)) < w$ **then** $width(info(q)) \leftarrow w$;
  end

This code is used in section 844.

847. At the end of a row, we append an unset box to the current vlist (for \halign) or the current hlist (for \valign). This unset box contains the unset boxes for the columns, separated by the tabskip glue. Everything will be set later.

procedure fin_row;
  var p: $pointer$;   {the new unset box}
  begin if $mode = -hmode$ **then**
    begin $p \leftarrow hpack(link(head), natural)$; pop_nest;
    if $cur\_pre\_head \neq cur\_pre\_tail$ **then** $append\_list(cur\_pre\_head)(cur\_pre\_tail)$;

      prototype box 852 ⟩;
  ⟨ Set the glue in all the unset boxes of the current list 853 ⟩;
  $flush\_node\_list(p)$; $pop\_alignment$; ⟨ Insert the current list into its environment 860 ⟩;
  end;
⟨ Declare the procedure called $align\_peek$ 833 ⟩

849. It's time now to dismantle the preamble list and to compute the column widths. Let w_{ij} be the maximum of the natural widths of all entries that span columns i through j, inclusive. The alignrecord for column i contains w_{ii} in its *width* field, and there is also a linked list of the nonzero w_{ij} for increasing j, accessible via the *info* field; these span nodes contain the value $j - i + min\_quarterword$ in their *link* fields. The values of w_{ii} were initialized to *null_flag*, which we regard as $-\infty$.

The final column widths are defined by the formula

$$w_j = \max_{1 \le i \le j} \left(w_{ij} - \sum_{i \le k < j} (t_k + w_k) \right),$$

where t_k is the natural width of the tabskip glue between columns k and $k + 1$. However, if $w_{ij} = -\infty$ for all i in the range $1 \le i \le j$ (i.e., if every entry that involved column j also involved column $j + 1$), we let $w_j = 0$, and we zero out the tabskip glue after column j.

TEX computes these values by using the following scheme: First $w_1 = w_{11}$. Then replace w_{2j} by $\max(w_{2j}, w_{1j} - t_1 - w_1)$, for all $j > 1$. Then $w_2 = w_{22}$. Then replace w_{3j} by $\max(w_{3j}, w_{2j} - t_2 - w_2)$ for all $j > 2$; and so on. If any w_j turns out to be $-\infty$, its value is changed to zero and so is the next tabskip.

⟨ Go through the preamble list, determining the column widths and changing the alignrecords to dummy
        unset boxes 849 ⟩ ≡
  $q \leftarrow link\,(preamble)$;
  repeat $flush\_list\,(u\_part\,(q))$; $flush\_list\,(v\_part\,(q))$; $p \leftarrow link\,(link\,(q))$;
    if $width\,(q) = null\_flag$ **then** ⟨ Nullify $width\,(q)$ and the tabskip glue following this column 850 ⟩;
    if $info\,(q) \ne end\_span$ **then**
      ⟨ Merge the widths in the span nodes of q with those of p, destroying the span nodes of q 851 ⟩;

  until $q = null$

This code is used in section 848.

850. ⟨ Nullify $width\,(q)$ and the tabskip glue following this column 850 ⟩ ≡
  begin $width\,(q) \leftarrow 0$; $r \leftarrow link\,(q)$; $s \leftarrow glue\_ptr\,(r)$;
  if $s \ne zero\_glue$ **then**
    begin $add\_glue\_ref\,(zero\_glue)$; $delete\_glue\_ref\,(s)$; $glue\_ptr\,(r) \leftarrow zero\_glue$;
    end;
  end

This code is used in section 849.

851.   Merging of two span-node lists is a typical exercise in the manipulation of linearly linked data structures. The essential invariant in the following **repeat** loop is that we want to dispense with node r, in q's list, and u is its successor; all nodes of p's list up to and including s have been processed, and the successor of s matches r or precedes r or follows r, according as $link(r) = n$ or $link(r) > n$ or $link(r) < n$.

$\langle$ Merge the widths in the span nodes of q with those of p, destroying the span nodes of q $\ 851 \rangle \equiv$

$\quad$**begin** $t \leftarrow width(q) + width(glue\_ptr(link(q)))$; $\ r \leftarrow info(q)$; $\ s \leftarrow end\_span$; $\ info(s) \leftarrow p$;
$\quad$$n \leftarrow min\_quarterword + 1$;
$\quad$**repeat** $width(r) \leftarrow width(r) - t$; $\ u \leftarrow info(r)$;
$\quad\quad$**while** $link(r) > n$ **do**
$\quad\quad\quad$**begin** $s \leftarrow info(s)$; $\ n \leftarrow link(info(s)) + 1$;
$\quad\quad\quad$**end**;
$\quad\quad$**if** $link(r) < n$ **then**
$\quad\quad\quad$**begin** $info(r) \leftarrow info(s)$; $\ info(s) \leftarrow r$; $\ decr(link(r))$; $\ s \leftarrow r$;
$\quad\quad\quad$**end**
$\quad\quad$**else begin if** $width(r) > width(info(s))$ **then** $\ width(info(s)) \leftarrow width(r)$;
$\quad\quad\quad$$free_node(r, span_node_size)$;
$\quad\quad\quad$**end**;
$\quad\quad$$r \leftarrow u$;
$\quad$**until** $r = end\_span$;
$\quad$**end**

This code is used in section 849.

852.   Now the preamble list has been converted to a list of alternating unset boxes and tabskip glue, where the box widths are equal to the final column sizes. In case of \valign, we change the widths to heights, so that a correct error message will be produced if the alignment is overfull or underfull.

$\langle$ Package the preamble list, to determine the actual tabskip glue amounts, and let p point to this prototype
$\quad\quad$ box $\ 852 \rangle \equiv$

$\quad$$save\_ptr \leftarrow save\_ptr - 2$; $\ pack\_begin\_line \leftarrow -mode\_line$;

            else *glue_set*$(r) \leftarrow$ *unfloat*$((height(r) - t)/glue\_shrink(r))$;

         end;

   height$(r) \leftarrow w$; *type*$(r) \leftarrow$ *vlist_node*;

   end

This code is used in section 856.

860. We now have a completed alignment, in the list that starts at *head* and ends at *tail*. This list will be merged with the one that encloses it. (In case the enclosing mode is *mmode*, for displayed formulas, we will need to insert glue before and after the display; that part of the program will be deferred until we're more familiar with such operations.)

   In restricted horizontal mode, the *clang* part of *aux* is undefined; an over-cautious Pascal runtime system may complain about this.

⟨Insert the current list into its environment 860⟩ ≡

   aux_save $\leftarrow$ *aux*; $p \leftarrow$ *link*$(head)$; $q \leftarrow$ *tail*; *pop_nest*;

   if *mode* = *mmode* **then** ⟨Finish an alignment in a display 1260⟩

   else begin *aux* $\leftarrow$ *aux_save*; *link*$(tail) \leftarrow p$;

      if $p \neq null$ **then** *tail* $\leftarrow q$;

      if *mode* = *vmode* **then** *build_page*;

      end

This code is used in section 848.

861.   Breaking paragraphs into lines.   We come now to what is probably the most interesting algorithm of TEX: the mechanism for choosing the "best possible" breakpoints that yield the individual lines of a paragraph. TEX's line-breaking algorithm takes a given horizontal list and converts it to a sequence of boxes that are appended to the current vertical list. In the course of doing this, it creates a special data structure containing three kinds of records that are not used elsewhere in TEX. Such nodes are created while a paragraph is being processed, and they are destroyed afterwards; thus, the other parts of TEX do not need to know anything about how line-breaking is done.

The method used here is based on an approach devised by Michael F. Plass and the author in 1977, subsequently generalized and improved by the same two people in 1980. A detailed discussion appears in *Software—Practice and Experience* **11** (1981), 1119–1184, where it is shown that the line-breaking problem can be regarded as a special case of the problem of computing the shortest path in an acyclic network. The cited paper includes numerous examples and describes the history of line breaking as it has been practiced by printers through the ages. The present implementation adds two new ideas to the algorithm of 1980: Memory space requirements are considerably reduced by using smaller records for inactive nodes than for active ones, and arithmetic overflow is avoided by using "delta distances" instead of keeping track of the total distance from the beginning of the paragraph to the current point.

862.   The *line_break* procedure should be invoked only in horizontal mode; it leaves that mode and places its output into the current vlist of the enclosing vertical mode (or internal vertical mode). There is one explicit parameter: *d* is true for partial paragraphs preceding display math mode; in this case the amount of additional penalty inserted before the final line is *display_widow_penalty* instead of *widow_penalty*.

There are also a number of implicit parameters: The hlist to be broken starts at *link*(*head*), and it is nonempty. The value of *prev_graf* in the enclosing semantic level tells where the paragraph should begin in the sequence of line numbers, in case hanging indentation or \parshape is in use; *prev_graf* is zero unless this paragraph is being continued after a displayed formula. Other implicit parameters, such as the *par_shape_ptr* and various penalties to use for hyphenation, etc., appear in *eqtb*.

After *line_break* has acted, it will have updated the current vlist and the value of *prev_graf*. Furthermore, the global variable *just_box* will point to the final box created by *line_break*, so that the width of this line can be ascertained when it is necessary to decide whether to use *above_display_skip* or *above_display_short_skip* before a displayed formula.

⟨ Global variables 13 ⟩ +≡
just_box: *pointer*;   { the *hlist_node* for the last line of the new paragraph }

863.   Since *line_break* is a rather lengthy procedure—sort of a small world unto itself—we must build it up little by little, somewhat more cautiously than we have done with the simpler procedures of TEX. Here is the general outline.

⟨ Declare subprocedures for *line_break* 874 ⟩
procedure *line_break*(*d* : *boolean*);
  label *done*, *done1*, *done2*, *done3*, *done4*, *done5*, *done6*, *continue*, *restart*;
  var ⟨ Local variables for line breaking 910 ⟩
  begin *pack_begin_line* ← *mode_line*;   { this is for over/underfull box messages }
  ⟨ Get ready to start line breaking 864 ⟩;
  ⟨ Find optimal breakpoints 911 ⟩;
  ⟨ Break the paragraph at the chosen breakpoints, justify the resulting lines to the correct widths, and
      append them to the current vertical list 924 ⟩;
  ⟨ Clean up the memory by removing the break nodes 913 ⟩;
  pack_begin_line ← 0;
  end;
⟨ Declare *ε*-TEX procedures for use by *main_control* 1466 ⟩

864.   The first task is to move the list from *head* to *temp_head* and go into the enclosing semantic level. We also append the `\parfillskip` glue to the end of the paragraph, removing a space (or other glue node) if it was there, since spaces usually precede blank lines and instances of '`$$`'. The *par_fill_skip* is preceded by an infinite penalty, so it will never be considered as a potential breakpoint.

This code assumes that a *glue_node* and a *penalty_node* occupy the same number of *mem* words.

⟨ Get ready to start line breaking 864 ⟩ ≡
  link(*temp_head*) ← *link*(*head*);
  if *is_char_node*(*tail*) **then** *tail_append*(*new_penalty*(*inf_penalty*))
  else if *type*(*tail*) ≠ *glue_node* **then** *tail_append*(*new_penalty*(*inf_penalty*))
    else begin *type*(*tail*) ← *penalty_node*; *delete_glue_ref*(*glue_ptr*(*tail*)); *flush_node_list*(*leader_ptr*(*tail*));
      penalty(*tail*) ← *inf_penalty*;
      end;
  link(*tail*) ← *new_param_glue*(*par_fill_skip_code*); *last_line_fill* ← *link*(*tail*);
  init_cur_lang ← *prev_graf* **mod** ´200000; *init_l_hyf* ← *prev_graf* **div** ´20000000;
  init_r_hyf ← (*prev_graf* **div** ´200000) **mod** ´100; *pop_nest*;
See also sections 875, 882, and 896.

This code is used in section 863.

865.   When looking for optimal line breaks, TEX creates a "break node" for each break that is *feasible*, in the sense that there is a way to end a line at the given place without requiring any line to stretch more than a given tolerance. A break node is characterized by three things: the position of the break (which is a pointer to a *glue_node*, *math_node*, *penalty_node*, or *disc_node*); the ordinal number of the line that will follow this breakpoint; and the fitness classification of the line that has just ended, i.e., *tight_fit*, *decent_fit*, *loose_fit*, or *very_loose_fit*.

  define *tight_fit* = 3   { fitness classification for lines shrinking 0.5 to 1.0 of their shrinkability }
  define *loose_fit* = 1   { fitness classification for lines stretching 0.5 to 1.0 of their stretchability }
  define *very_loose_fit* = 0   { fitness classification for lines stretching more than their stretchability }
  define *decent_fit* = 2   { fitness classification for all other lines }

866.   The algorithm essentially determines the best possible way to achieve each feasible combination of position, line, and fitness. Thus, it answers questions like, "What is the best way to break the opening part of the paragraph so that the fourth line is a tight line ending at such-and-such a place?" However, the fact that all lines are to be the same length after a certain point makes it possible to regard all sufficiently large line numbers as equivalent, when the looseness parameter is zero, and this makes it possible for the algorithm to save space and time.

An "active node" and a "passive node" are created in *mem* for each feasible breakpoint that needs to be considered. Active nodes are three words long and passive nodes are two words long. We need active nodes only for breakpoints near the place in the paragraph that is currently being examined, so they are recycled within a comparatively short time after they are created.

867.   An active node for a given breakpoint contains six fields:

link points to the next node in the list of active nodes; the last active node has *link* = *last_active*.

break_node points to the passive node associated with this breakpoint.

line_number is the number of the line that follows this breakpoint.

fitness is the fitness classification of the line ending at this breakpoint.

type is either *hyphenated* or *unhyphenated*, depending on whether this breakpoint is a *disc_node*.

total_demerits is the minimum possible sum of demerits over all lines leading from the beginning of the paragraph to this breakpoint.

The value of *link*(*active*) points to the first active node on a linked list of all currently active nodes. This list is in order by *line_number*, except that nodes with *line_number* > *easy_line* may be in any order relative to each other.

> **define** *active_node_size_normal* = 3   { number of words in normal active nodes }
> **define** *fitness* ≡ *subtype*   { *very_loose_fit* .. *tight_fit* on final line for this break }
> **define** *break_node* ≡ *rlink*   { pointer to the corresponding passive node }
> **define** *line_number* ≡ *llink*   { line that begins at this breakpoint }
> **define** *total_demerits*(#) ≡ *mem*[# + 2].*int*   { the quantity that TEX minimizes }
> **define** *unhyphenated* = 0   { the *type* of a normal active break node }
> **define** *hyphenated* = 1   { the *type* of an active node that breaks at a *disc_node* }
> **define** *last_active* ≡ *active*   { the active list ends where it begins }

868.   ⟨ Initialize the special list heads and constant nodes 838 ⟩ +≡
> *type*(*last_active*) ← *hyphenated*; *line_number*(*last_active*) ← *max_halfword*; *subtype*(*last_active*) ← 0;
>   { the *subtype* is never examined by the algorithm }

869.   The passive node for a given breakpoint contains only four fields:

link points to the passive node created just before this one, if any, otherwise it is *null*.

cur_break points to the position of this breakpoint in the horizontal list for the paragraph being broken.

prev_break points to the passive node that should precede this one in an optimal path to this breakpoint.

serial is equal to *n* if this passive node is the *n*th one created during the current pass. (This field is used only when printing out detailed statistics about the line-breaking calculations.)

There is a global variable called *passive* that points to the most recently created passive node. Another global variable, *printed_node*, is used to help print out the paragraph when detailed information about the line-breaking computation is being displayed.

> **define** *passive_node_size* = 2   { number of words in passive nodes }
> **define** *cur_break* ≡ *rlink*   { in passive node, points to position of this breakpoint }
> **define** *prev_break* ≡ *llink*   { points to passive node that should precede this one }
> **define** *serial* ≡ *info*   { serial number for symbolic identification }

⟨ Global variables 13 ⟩ +≡
passive: *pointer*;   { most recent node on passive list }
printed_node: *pointer*;   { most recent node that has been printed }
pass_number: *halfword*;   { the number of passive nodes allocated on this pass }

870.   The active list also contains "delta" nodes that help the algorithm compute the badness of individual lines. Such nodes appear only between two active nodes, and they have $type = delta\_node$. If p and r are active nodes and if q is a delta node between them, so that $link(p) = q$ and $link(q) = r$, then q tells the space difference between lines in the horizontal list that start after breakpoint p and lines that start after breakpoint r. In other words, if we know the length of the line that starts after p and ends at our current position, then the corresponding length of the line that starts after r is obtained by adding the amounts in node q. A delta node contains six scaled numbers, since it must record the net change in glue stretchability with respect to all orders of infinity. The natural width difference appears in $mem[q + 1].sc$; the stretch differences in units of pt, fil, fill, and filll appear in $mem[q + 2 .. q + 5].sc$; and the shrink difference appears in $mem[q + 6].sc$. The $subtype$ field of a delta node is not used.

> **define** $delta\_node\_size = 7$ { number of words in a delta node }
> **define** $delta\_node = 2$ { $type$ field in a delta node }

871.   As the algorithm runs, it maintains a set of six delta-like registers for the length of the line following the first active breakpoint to the current position in the given hlist. When it makes a pass through the active list, it also maintains a similar set of six registers for the length following the active breakpoint of current interest. A third set holds the length of an empty line (namely, the sum of \leftskip and \rightskip); and a fourth set is used to create new delta nodes.

When we pass a delta node we want to do operations like

$$\textbf{for } k \leftarrow 1 \textbf{ to } 6 \textbf{ do } cur\_active\_width[k] \leftarrow cur\_active\_width[k] + mem[q + k].sc;$$

and we want to do this without the overhead of **for** loops. The do_all_six macro makes such six-tuples convenient.

> **define** $do\_all\_six(\#) \equiv \#(1);\ \#(2);\ \#(3);\ \#(4);\ \#(5);\ \#(6)$

⟨ Global variables 13 ⟩ +≡
$active\_width$: **array** $[1 .. 6]$ **of** $scaled$;   { distance from first active node to cur_p }
cur_active_width: **array** $[1 .. 6]$ **of** $scaled$;   { distance from current active node }
$background$: **array** $[1 .. 6]$ **of** $scaled$;   { length of an "empty" line }
$break\_width$: **array** $[1 .. 6]$ **of** $scaled$;   { length being computed after current break }

872.   Let's state the principles of the delta nodes more precisely and concisely, so that the following programs will be less obscure. For each legal breakpoint p in the paragraph, we define two quantities $\alpha(p)$ and $\beta(p)$ such that the length of material in a line from breakpoint p to breakpoint q is $\gamma + \beta(q) - \alpha(p)$, for some fixed γ. Intuitively, $\alpha(p)$ and $\beta(q)$ are the total length of material from the beginning of the paragraph to a point "after" a break at p and to a point "before" a break at q; and γ is the width of an empty line, namely the length contributed by \leftskip and \rightskip.

Suppose, for example, that the paragraph consists entirely of alternating boxes and glue skips; let the boxes have widths $x_1 \ldots x_n$ and let the skips have widths $y_1 \ldots y_n$, so that the paragraph can be represented by $x_1 y_1 \ldots x_n y_n$. Let p_i be the legal breakpoint at y_i; then $\alpha(p_i) = x_1 + y_1 + \cdots + x_i + y_i$, and $\beta(p_i) = x_1 + y_1 + \cdots + x_i$. To check this, note that the length of material from p_2 to p_5, say, is $\gamma + x_3 + y_3 + x_4 + y_4 + x_5 = \gamma + \beta(p_5) - \alpha(p_2)$.

The quantities α, β, γ involve glue stretchability and shrinkability as well as a natural width. If we were to compute $\alpha(p)$ and $\beta(p)$ for each p, we would need multiple precision arithmetic, and the multiprecise numbers would have to be kept in the active nodes. TEX avoids this problem by working entirely with relative differences or "deltas." Suppose, for example, that the active list contains $a_1\,\delta_1\,a_2\,\delta_2\,a_3$, where the a's are active breakpoints and the δ's are delta nodes. Then $\delta_1 = \alpha(a_1) - \alpha(a_2)$ and $\delta_2 = \alpha(a_2) - \alpha(a_3)$. If the line breaking algorithm is currently positioned at some other breakpoint p, the *active_width* array contains the value $\gamma + \beta(p) - \alpha(a_1)$. If we are scanning through the list of active nodes and considering a tentative line that runs from a_2 to p, say, the *cur_active_width* array will contain the value $\gamma + \beta(p) - \alpha(a_2)$. Thus, when we move from a_2 to a_3, we want to add $\alpha(a_2) - \alpha(a_3)$ to *cur_active_width*; and this is just δ_2, which appears in the active list between a_2 and a_3. The *background* array contains γ. The *break_width* array will be used to calculate values of new delta nodes when the active list is being updated.

873.   Glue nodes in a horizontal list that is being paragraphed are not supposed to include "infinite" shrinkability; that is why the algorithm maintains four registers for stretching but only one for shrinking. If the user tries to introduce infinite shrinkability, the shrinkability will be reset to finite and an error message will be issued. A boolean variable *no_shrink_error_yet* prevents this error message from appearing more than once per paragraph.

> **define** *check_shrinkage*(#) ≡
>   **if** $(shrink\_order(\#) \neq normal) \wedge (shrink(\#) \neq 0)$ **then**
>   **begin** # ← *finite_shrink*(#);
>   **end**

  background[6] ← *shrink*(*q*) + *shrink*(*r*); ⟨Check for special treatment of last line of paragraph 1654⟩;

876. A pointer variable *cur_p* runs through the given horizontal list as we look for breakpoints. This variable is global, since it is used both by *line_break* and by its subprocedure *try_break*.

Another global variable called *threshold* is used to determine the feasibility of individual lines: Breakpoints are feasible if there is a way to reach them without creating lines whose badness exceeds *threshold*. (The badness is compared to *threshold* before penalties are added, so that penalty values do not affect the feasibility of breakpoints, except that no break is allowed when the penalty is 10000 or more.) If *threshold* is 10000 or more, all legal breaks are considered feasible, since the *badness* function specified above never returns a value greater than 10000.

Up to three passes might be made through the paragraph in an attempt to find at least one set of feasible breakpoints. On the first pass, we have *threshold* = *pretolerance* and *second_pass* = *final_pass* = *false*. If this pass fails to find a feasible solution, *threshold* is set to *tolerance*, *second_pass* is set *true*, and an attempt is made to hyphenate as many words as possible. If that fails too, we add *emergency_stretch* to the background stretchability and set *final_pass* = *true*.

⟨Global variables 13⟩ +≡
cur_p: *pointer*;   {the current breakpoint under consideration}
second_pass: *boolean*;   {is this our second attempt to break this paragraph?}
final_pass: *boolean*;   {is this our final attempt to break this paragraph?}
threshold: *integer*;   {maximum badness on feasible lines}

877.   The heart of the line-breaking procedure is '*try_break*', a subroutine that tests if the current breakpoint
cur_p is feasible, by running through the active list to see what lines of text can be made from active nodes
to *cur_p*. If feasible breaks are possible, new break nodes are created. If *cur_p* is too far from an active
node, that node is deactivated.

The parameter *pi* to *try_break* is the penalty associated with a break at *cur_p*; we have *pi* = *eject_penalty*
if the break is forced, and *pi* = *inf_penalty* if the break is illegal.

The other parameter, *break_type*, is set to *hyphenated* or *unhyphenated*, depending on whether or not
the current break is at a *disc_node*. The end of a paragraph is also regarded as '*hyphenated*'; this case is
distinguishable by the condition *cur_p* = *null*.

880.   The following code uses the fact that $type(last\_active) \neq delta\_node$.

> **define** $update\_width(\#) \equiv cur\_active\_width[\#] \leftarrow cur\_active\_width[\#] + mem[r + \#].sc$

⟨If node r is of type $delta\_node$, update cur_active_width, set $prev\_r$ and $prev\_prev\_r$, then **goto**
     $continue$ 880⟩ ≡
  if $type(r) = delta\_node$ **then**
     begin $do\_all\_six(update\_width)$; $prev\_prev\_r \leftarrow prev\_r$; $prev\_r \leftarrow r$; **goto** $continue$;
     end

This code is used in section 877.

881.   As we consider various ways to end a line at cur_p, in a given line number class, we keep track of the
best total demerits known, in an array with one entry for each of the fitness classifications. For example,
$minimal\_demerits[tight\_fit]$ contains the fewest total demerits of feasible line breaks ending at cur_p with
a $tight\_fit$ line; $best\_place[tight\_fit]$ points to the passive node for the break before cur_p that achieves
such an optimum; and $best\_pl\_line[tight\_fit]$ is the $line\_number$ field in the active node corresponding to
$best\_place[tight\_fit]$. When no feasible break sequence is known, the $minimal\_demerits$ entries will be equal
to $awful\_bad$, which is $2^{30} - 1$. Another variable, $minimum\_demerits$, keeps track of the smallest value in
the $minimal\_demerits$ array.

> **define** $awful\_bad \equiv ´7777777777$ { more than a billion demerits }

⟨Global variables 13⟩ +≡
$minimal\_demerits$: **array** $[very\_loose\_fit .. tight\_fit]$ **of** $integer$;

$best\_pl\_line$: **array** $[very\_loose\_fit .. tight\_fit]$ **of** $halfword$;   { corresponding line number }

882.   ⟨Get ready to start line breaking 864⟩ +≡
  $minimum\_demerits \leftarrow awful\_bad$; $minimal\_demerits[tight\_fit] \leftarrow awful\_bad$;
  $minimal\_demerits[decent\_fit] \leftarrow awful\_bad$; $minimal\_demerits[loose\_fit] \leftarrow awful\_bad$;
  $minimal\_demerits[very\_loose\_fit] \leftarrow awful\_bad$;

883.   The first part of the following code is part of TEX's inner loop, so we don't want to waste any time.
The current active node, namely node r, contains the line number that will be considered next. At the end
of the list we have arranged the data structure so that $r = last\_active$ and $line\_number(last\_active) > old\_l$.

⟨If a line number class has ended, create new active nodes for the best feasible breaks in that class; then
     return if $r = last\_active$, otherwise compute the new $line\_width$ 883⟩ ≡
  begin $l \leftarrow line\_number(r)$;
  if $l > old\_l$ **then**
     begin   { now we are no longer in the inner loop }
     if $(minimum\_demerits < awful\_bad) \wedge ((old\_l \neq easy\_line) \vee (r = last\_active))$ **then**
       ⟨Create new active nodes for the best feasible breaks just found 884⟩;
     if $r = last\_active$ **then** **return**;
     ⟨Compute the new line width 898⟩;
     end;
  end

This code is used in section 877.

884. It is not necessary to create new active nodes having *minimal_demerits* greater than *minimum_demerits* + *abs*(*adj_demerits*), since such active nodes will never be chosen in the final paragraph breaks. This observation allows us to omit a substantial number of feasible breakpoints from further consideration.

⟨Create new active nodes for the best feasible breaks just found 884⟩ ≡
  begin if *no_break_yet* **then** ⟨Compute the values of *break_width* 885⟩;
  ⟨Insert a delta node to prepare for breaks at *cur_p* 891⟩;

    begin if *minimal_demerits*[*fit_class*] ≤ *minimum_demerits* **then**
      ⟨Insert a new active node from *best_place*[*fit_class*] to *cur_p* 893⟩;
    minimal_demerits[*fit_class*] ← *awful_bad*;
    end;
  minimum_demerits ← *awful_bad*; ⟨Insert a delta node to prepare for the next active node 892⟩;
  end

This code is used in section 883.

885. When we insert a new active node for a break at *cur_p*, suppose this new node is to be placed just before active node *a*; then we essentially want to insert '*δ cur_p δ′*' before *a*, where *δ* = *α*(*a*) − *α*(*cur_p*) and *δ′* = *α*(*cur_p*) − *α*(*a*) in the notation explained above. The *cur_active_width* array now holds *γ* + *β*(*cur_p*) − *α*(*a*); so *δ* can be obtained by subtracting *cur_active_width* from the quantity *γ* + *β*(*cur_p*) − *α*(*cur_p*). The latter quantity can be regarded as the length of a line "from *cur_p* to *cur_p*"; we call it the *break_width* at *cur_p*.

The *break_width* is usually negative, since it consists of the background (which is normally zero) minus the width of nodes following *cur_p* that are eliminated after a break. If, for example, node *cur_p* is a glue node, the width of this glue is subtracted from the background; and we also look ahead to eliminate all subsequent glue and penalty and kern and math nodes, subtracting their widths as well.

Kern nodes do not disappear at a line break unless they are *explicit* or *space_adjustment*.

  define *set_break_width_to_background*(#) ≡ *break_width*[#] ← *background*[#]

⟨Compute the values of *break_width* 885⟩ ≡
  begin *no_break_yet* ← *false*; *do_all_six*(*set_break_width_to_background*); *s* ← *cur_p*;
  if *break_type* > *unhyphenated* **then**
    if *cur_p* ≠ *null* **then** ⟨Compute the discretionary *break_width* values 888⟩;
  while *s* ≠ *null* **do**
    begin if *is_char_node*(*s*) **then goto** *done*;
    case *type*(*s*) **of**
    glue_node: ⟨Subtract glue from *break_width* 886⟩;
    penalty_node: *do_nothing*;
    math_node: *break_width*[1] ← *break_width*[1] − *width*(*s*);
    kern_node: **if** *subtype*(*s*) ≠ *explicit* **then goto** *done*
      else *break_width*[1] ← *break_width*[1] − *width*(*s*);
    othercases goto *done*
    endcases;
    s ← *link*(*s*);
    end;
done: **end**

This code is used in section 884.

886. ⟨Subtract glue from *break_width* 886⟩ ≡
  begin $v \leftarrow$ *glue_ptr*(*s*); *break_width*[1] $\leftarrow$ *break_width*[1] $-$ *width*(*v*);
  break_width[2 + *stretch_order*(*v*)] $\leftarrow$ *break_width*[2 + *stretch_order*(*v*)] $-$ *stretch*(*v*);
  break_width[6] $\leftarrow$ *break_width*[6] $-$ *shrink*(*v*);
  end

This code is used in section 885.

887. When *cur_p* is a discretionary break, the length of a line "from *cur_p* to *cur_p*" has to be defined properly so that the other calculations work out. Suppose that the pre-break text at *cur_p* has length l_0, the post-break text has length l_1, and the replacement text has length l. Suppose also that q is the node following the replacement text. Then length of a line from *cur_p* to q will be computed as $\gamma + \beta(q) - \alpha(\mathit{cur\_p})$, where $\beta(q) = \beta(\mathit{cur\_p}) - l_0 + l$. The actual length will be the background plus l_1, so the length from *cur_p* to *cur_p* should be $\gamma + l_0 + l_1 - l$. If the post-break text of the discretionary is empty, a break may also discard q; in that unusual case we subtract the length of q and any other nodes that will be discarded after the discretionary break.

  The value of l_0 need not be computed, since *line_break* will put it into the global variable *disc_width* before calling *try_break*.

⟨Global variables 13⟩ +≡
disc_width: *scaled*;   { the length of discretionary material preceding a break }

888. ⟨Compute the discretionary *break_width* values 888⟩ ≡
  begin $t \leftarrow$ *replace_count*(*cur_p*); $v \leftarrow$ *cur_p*; $s \leftarrow$ *post_break*(*cur_p*);
  while $t > 0$ **do**
    begin *decr*(*t*); $v \leftarrow$ *link*(*v*); ⟨Subtract the width of node *v* from *break_width* 889⟩;
    end;
  while $s \neq$ *null* **do**
    begin ⟨Add the width of node *s* to *break_width* 890⟩;
    $s \leftarrow$ *link*(*s*);
    end;

  if $prev\_break(passive) = null$ **then** $print\_char("0")$
  else $print\_int(serial(prev\_break(passive)))$;
  end

This code is used in section 893.

895.   The length of lines depends on whether the user has specified \parshape or \hangindent. If *par_shape_ptr* is not null, it points to a $(2n + 1)$-word record in *mem*, where the *info* in the first word contains the value of n, and the other $2n$ words contain the left margins and line lengths for the first n lines of the paragraph; the specifications for line n apply to all subsequent lines. If *par_shape_ptr* = *null*, the shape of the paragraph depends on the value of $n = hang\_after$; if $n \geq 0$, hanging indentation takes place on lines $n + 1$, $n + 2$, ..., otherwise it takes place on lines 1, ..., $|n|$. When hanging indentation is active, the left margin is *hang_indent*, if *hang_indent* ≥ 0, else it is 0; the line length is $hsize - |hang\_indent|$. The normal setting is *par_shape_ptr* = *null*, *hang_after* = 1, and *hang_indent* = 0. Note that if *hang_indent* = 0, the value of *hang_after* is irrelevant.

⟨Global variables 13⟩ +≡
easy_line: *halfword*;   {line numbers > *easy_line* are equivalent in break nodes}
last_special_line: *halfword*;   {line numbers > *last_special_line* all have the same width}
first_width: *scaled*;   {the width of all lines ≤ *last_special_line*, if no \parshape has been specified}
second_width: *scaled*;   {the width of all lines > *last_special_line*}
first_indent: *scaled*;   {left margin to go with *first_width*}
second_indent: *scaled*;   {left margin to go with *second_width*}

896.   We compute the values of *easy_line* and the other local variables relating to line length when the *line_break* procedure is initializing itself.

⟨ Get ready to start line breaking 864 ⟩ +≡
  if *par_shape_ptr* = *null* **then**
    if *hang_indent* = 0 **then**
      begin *last_special_line* ← 0; *second_width* ← *hsize*; *second_indent* ← 0;
      end
    else ⟨ Set line length parameters in preparation for hanging indentation 897 ⟩
  else begin *last_special_line* ← *info*(*par_shape_ptr*) − 1;
    second_width ← *mem*[*par_shape_ptr* + 2 ∗ (*last_special_line* + 1)].*sc*;
    second_indent ← *mem*[*par_shape_ptr* + 2 ∗ *last_special_line* + 1].*sc*;
    end;
  if *looseness* = 0 **then** *easy_line* ← *last_special_line*
  else *easy_line* ← *max_halfword*

897.   ⟨ Set line length parameters in preparation for hanging indentation 897 ⟩ ≡
  begin *last_special_line* ← *abs*(*hang_after*);
  if *hang_after* < 0 **then**
    begin *first_width* ← *hsize* − *abs*(*hang_indent*);
    if *hang_indent* ≥ 0 **then** *first_indent* ← *hang_indent*
    else *first_indent* ← 0;
    second_width ← *hsize*; *second_indent* ← 0;
    end
  else begin *first_width* ← *hsize*; *first_indent* ← 0; *second_width* ← *hsize* − *abs*(*hang_indent*);
    if *hang_indent* ≥ 0 **then** *second_indent* ← *hang_indent*
    else *second_indent* ← 0;
    end;
  end

This code is used in section 896.

898.   When we come to the following code, we have just encountered the first active node *r* whose *line_number* field contains *l*. Thus we want to compute the length of the *l*th line of the current paragraph. Furthermore, we want to set *old_l* to the last number in the class of line numbers equivalent to *l*.

⟨ Compute the new line width 898 ⟩ ≡
  if *l* > *easy_line* **then**
    begin *line_width* ← *second_width*; *old_l* ← *max_halfword* − 1;
    end
  else begin *old_l* ← *l*;
    if *l* > *last_special_line* **then** *line_width* ← *second_width*
    else if *par_shape_ptr* = *null* **then** *line_width* ← *first_width*
      else *line_width* ← *mem*[*par_shape_ptr* + 2 ∗ *l*].*sc*;
    end

This code is used in section 883.

899. The remaining part of *try_break* deals with the calculation of demerits for a break from r to *cur_p*.

The first thing to do is calculate the badness, b. This value will always be between zero and *inf_bad* $+ 1$; the latter value occurs only in the case of lines from r to *cur_p* that cannot shrink enough to fit the necessary width. In such cases, node r will be deactivated. We also deactivate node r when a break at *cur_p* is forced, since future breaks must go through a forced break.

⟨ Consider the demerits for a line from r to *cur_p*; deactivate node r if it should no longer be active; then
   goto *continue* if a line from r to *cur_p* is infeasible, otherwise record a new feasible break 899 ⟩ ≡
 begin *artificial_demerits* ← *false*;
 shortfall ← *line_width* − *cur_active_width*[1]; { we're this much too short }
 if *XeTeX_protrude_chars* > 1 **then** *shortfall* ← *shortfall* + *total_pw*(*r*, *cur_p*);
 if *shortfall* > 0 **then**
  ⟨ Set the value of b to the badness for stretching the line, and compute the corresponding *fit_class* 900 ⟩
 else ⟨ Set the value of b to the badness for shrinking the line, and compute the corresponding
   fit_class 901 ⟩;
 if *do_last_line_fit* **then** ⟨ Adjust the additional data for last line 1660 ⟩;
found: **if** (b > *inf_bad*) ∨ (*pi* = *eject_penalty*) **then** ⟨ Prepare to deactivate node r, and **goto** *deactivate*
   unless there is a reason to consider lines of text from r to *cur_p* 902 ⟩
 else begin *prev_r* ← *r*;
  if b > *threshold* **then goto** *continue*;
  node_r_stays_active ← *true*;
  end;
 ⟨ Record a new feasible break 903 ⟩;
 if *node_r_stays_active* **then goto** *continue*; { *prev_r* has been set to r }
deactivate: ⟨ Deactivate node r 908 ⟩;
 end

This code is used in section 877.

900.   When a line must stretch, the available stretchability can be found in the subarray *cur_active_width*[2 . . 5], in units of points, fil, fill, and filll.

The present section is part of TEX's inner loop, and it is most often performed when the badness is infinite; therefore it is worth while to make a quick test for large width excess and small stretchability, before calling the *badness* subroutine.

⟨ Set the value of *b* to the badness for stretching the line, and compute the corresponding *fit_class* 900 ⟩ ≡
  if (*cur_active_width*[3] ≠ 0) ∨ (*cur_active_width*[4] ≠ 0) ∨ (*cur_active_width*[5] ≠ 0) **then**
    begin if *do_last_line_fit* **then**
      begin if *cur_p* = *null* **then**   { the last line of a paragraph }
        ⟨ Perform computations for last line and **goto** *found* 1657 ⟩;
      shortfall ← 0;
      end;
    b ← 0; *fit_class* ← *decent_fit*;   { infinite stretch }
    end
  else begin if *shortfall* > 7230584 **then**
    if *cur_active_width*[2] < 1663497 **then**
      begin *b* ← *inf_bad*; *fit_class* ← *very_loose_fit*; **goto** *done1*;
      end;
    b ← *badness*(*shortfall*, *cur_active_width*[2]);
    if *b* > 12 **then**
      if *b* > 99 **then** *fit_class* ← *very_loose_fit*
      else *fit_class* ← *loose_fit*
    else *fit_class* ← *decent_fit*;
  done1: **end**

This code is used in section 899.

901.   Shrinkability is never infinite in a paragraph; we can shrink the line from *r* to *cur_p* by at most *cur_active_width*[6].

⟨ Set the value of *b* to the badness for shrinking the line, and compute the corresponding *fit_class* 901 ⟩ ≡
  begin if −*shortfall* > *cur_active_width*[6] **then** *b* ← *inf_bad* + 1
  else *b* ← *badness*(−*shortfall*, *cur_active_width*[6]);
  if *b* > 12 **then** *fit_class* ← *tight_fit* **else** *fit_class* ← *decent_fit*;
  end

This code is used in section 899.

902.   During the final pass, we dare not lose all active nodes, lest we lose touch with the line breaks already found. The code shown here makes sure that such a catastrophe does not happen, by permitting overfull boxes as a last resort. This particular part of TEX was a source of several subtle bugs before the correct program logic was finally discovered; readers who seek to "improve" TEX should therefore think thrice before daring to make any changes here.

⟨ Prepare to deactivate node *r*, and **goto** *deactivate* unless there is a reason to consider lines of text from *r* to *cur_p* 902 ⟩ ≡
  begin if *final_pass* ∧ (*minimum_demerits* = *awful_bad*) ∧ (*link*(*r*) = *last_active*) ∧ (*prev_r* = *active*) **then**
    artificial_demerits ← *true*   { set demerits zero, this break is forced }
  else if *b* > *threshold* **then goto** *deactivate*;
  node_r_stays_active ← *false*;
  end

This code is used in section 899.

903. When we get to this part of the code, the line from r to cur_p is feasible, its badness is b, and its fitness classification is *fit_class*. We don't want to make an active node for this break yet, but we will compute the total demerits and record them in the *minimal_demerits* array, if such a break is the current champion among all ways to get to cur_p in a given line-number class and fitness class.

⟨Record a new feasible break 903⟩ ≡
  if *artificial_demerits* **then** $d \leftarrow 0$
  else ⟨Compute the demerits, d, from r to cur_p 907⟩;
  stat if *tracing_paragraphs* > 0 **then** ⟨Print a symbolic description of this feasible break 904⟩;
  tats
  $d \leftarrow d + total\_demerits(r)$;   { this is the minimum total demerits from the beginning to cur_p via r }
  if $d \leq minimal\_demerits[fit\_class]$ **then**
    begin $minimal\_demerits[fit\_class] \leftarrow d$; $best\_place[fit\_class] \leftarrow break\_node(r)$; $best\_pl\_line[fit\_class] \leftarrow l$;
    if *do_last_line_fit* **then** ⟨Store additional data for this feasible break 1661⟩;
    if $d < minimum\_demerits$ **then** $minimum\_demerits \leftarrow d$;
    end

This code is used in section 899.

904. ⟨Print a symbolic description of this feasible break 904⟩ ≡
  begin if *printed_node* $\neq cur\_p$ **then**
    ⟨Print the list between *printed_node* and cur_p, then set *printed_node* $\leftarrow cur\_p$ 905⟩;
  $print\_nl("@")$;
  if $cur\_p = null$ **then** $print\_esc("par")$
  else if $type(cur\_p) \neq glue\_node$ **then**

  else $print\_int(serial(break\_node(r)))$;
  $print("\textvisiblespace b=")$;
  if $b > inf\_bad$ **then** $print\_char("*")$ **else** $print\_int(b)$;
  $print("\textvisiblespace p=")$; $print\_int(pi)$; $print("\textvisiblespace d=")$;
  if *artificial_demerits* **then** $print\_char("*")$ **else** $print\_int(d)$;
  end

This code is used in section 903.

905. ⟨Print the list between *printed_node* and cur_p, then set *printed_node* $\leftarrow cur\_p$ 905⟩ ≡
  begin $print\_nl("")$;
  if $cur\_p = null$ **then** $short\_display(link(printed\_node))$
  else begin $save\_link \leftarrow link(cur\_p)$; $link(cur\_p) \leftarrow null$; $print\_nl("")$;
    $short\_display(link(printed\_node))$; $link(cur\_p) \leftarrow save\_link$;
    end;
  $printed\_node \leftarrow cur\_p$;
  end

This code is used in section 904.

906.   When the data for a discretionary break is being displayed, we will have printed the *pre_break* and *post_break* lists; we want to skip over the third list, so that the discretionary data will not appear twice. The following code is performed at the very end of *try_break*.

⟨Update the value of *printed_node* for symbolic displays 906⟩ ≡
  if *cur_p* = *printed_node* **then**
    if *cur_p* ≠ *null* **then**
      if *type*(*cur_p*) = *disc_node* **then**
        begin *t* ← *replace_count*(*cur_p*);
        while *t* > 0 **do**
          begin *decr*(*t*); *printed_node* ← *link*(*printed_node*);
          end;
        end

This code is used in section 877.

907.   ⟨Compute the demerits, *d*, from *r* to *cur_p* 907⟩ ≡
  begin *d* ← *line_penalty* + *b*;
  if *abs*(*d*) ≥ 10000 **then** *d* ← 100000000 **else** *d* ← *d* * *d*;
  if *pi* ≠ 0 **then**
    if *pi* > 0 **then** *d* ← *d* + *pi* * *pi*
    else if *pi* > *eject_penalty* **then** *d* ← *d* − *pi* * *pi*;
  if (*break_type* = *hyphenated*) ∧ (*type*(*r*) = *hyphenated*) **then**
    if *cur_p* ≠ *null* **then** *d* ← *d* + *double_hyphen_demerits*
    else *d* ← *d* + *final_hyphen_demerits*;
  if *abs*(*fit_class* − *fitness*(*r*)) > 1 **then** *d* ← *d* + *adj_demerits*;
  end

This code is used in section 903.

908.   When an active node disappears, we must delete an adjacent delta node if the active node was at the beginning or the end of the active list, or if it was surrounded by delta nodes. We also must preserve the property that *cur_active_width* represents the length of material from *link*(*prev_r*) to *cur_p*.

  define *combine_two_deltas*(#) ≡ *mem*[*prev_r* + #].*sc* ← *mem*[*prev_r* + #].*sc* + *mem*[*r* + #].*sc*
  define *downdate_width*(#) ≡ *cur_active_width*[#] ← *cur_active_width*[#] − *mem*[*prev_r* + #].*sc*

⟨Deactivate node *r* 908⟩ ≡
  link(*prev_r*) ← *link*(*r*); *free_node*(*r*, *active_node_size*);
  if *prev_r* = *active* **then** ⟨Update the active widths, since the first active node has been deleted 909⟩
  else if *type*(*prev_r*) = *delta_node* **then**
    begin *r* ← *link*(*prev_r*);
    if *r* = *last_active* **then**
      begin *do_all_six*(*downdate_width*); *link*(*prev_prev_r*) ← *last_active*;
      free_node(*prev_r*, *delta_node_size*); *prev_r* ← *prev_prev_r*;
      end
    else if *type*(*r*) = *delta_node* **then**
      begin *do_all_six*(*update_width*); *do_all_six*(*combine_two_deltas*); *link*(*prev_r*) ← *link*(*r*);
      free_node(*r*, *delta_node_size*);
      end;
    end

This code is used in section 899.

909.   The following code uses the fact that $type(last\_active) \neq delta\_node$. If the active list has just become empty, we do not need to update the *active_width* array, since it will be initialized when an active node is next inserted.

> **define** $update\_active(\#) \equiv active\_width[\#] \leftarrow active\_width[\#] + mem[r + \#].sc$

⟨ Update the active widths, since the first active node has been deleted 909 ⟩ ≡
> **begin** $r \leftarrow link(active)$;
> **if** $type(r) = delta\_node$ **then**
> > **begin** $do\_all\_six(update\_active)$; $do\_all\_six(copy\_to\_cur\_active)$; $link(active) \leftarrow link(r)$;
> > $free\_node(r, delta\_node\_size)$;
> > **end**;
>
> **end**

This code is used in section 908.

910. Breaking paragraphs into lines, continued.   So far we have gotten a little way into the *line_break* routine, having covered its important *try_break* subroutine. Now let's consider the rest of the process.

The main loop of *line_break* traverses the given hlist, starting at *link*(*temp_head*), and calls *try_break* at each legal breakpoint. A variable called *auto_breaking* is set to true except within math formulas, since glue nodes are not legal breakpoints when they appear in formulas.

The current node of interest in the hlist is pointed to by *cur_p*. Another variable, *prev_p*, is usually one step behind *cur_p*, but the real meaning of *prev_p* is this: If *type*(*cur_p*) = *glue_node* then *cur_p* is a legal breakpoint if and only if *auto_breaking* is true and *prev_p* does not point to a glue node, penalty node, explicit kern node, or math node.

The following declarations provide for a few other local variables that are used in special calculations.

⟨ Local variables for line breaking 910 ⟩ ≡
auto_breaking: *boolean*;   { is node *cur_p* outside a formula? }
prev_p: *pointer*;   { helps to determine when glue nodes are breakpoints }
q, r, s, prev_s: *pointer*;   { miscellaneous nodes of temporary interest }
f: *internal_font_number*;   { used when calculating character widths }
See also sections 942 and 948.

This code is used in section 863.

911.   The 'loop' in the following code is performed at most thrice per call of *line_break*, since it is actually a pass over the entire paragraph.

> **define** *update_prev_p* ≡
> > **begin** *prev_p* ← *cur_p*; *global_prev_p* ← *cur_p*;
> > **end**

⟨Find optimal breakpoints 911⟩ ≡
> *threshold* ← *pretolerance*;
> **if** *threshold* ≥ 0 **then**
> > **begin stat if** *tracing_paragraphs* > 0 **then**
> > > **begin** *begin_diagnostic*; *print_nl*("@firstpass"); **end**; **tats**
> > *second_pass* ← *false*; *final_pass* ← *false*;
> > **end**
> **else begin** *threshold* ← *tolerance*; *second_pass* ← *true*; *final_pass* ← (*emergency_stretch* ≤ 0);
> > **stat if** *tracing_paragraphs* > 0 **then** *begin_diagnostic*;
> > **tats**
> > **end**;
> **loop begin if** *threshold* > *inf_bad* **then** *threshold* ← *inf_bad*;
> > **if** *second_pass* **then** ⟨Initialize for hyphenating a paragraph 939⟩;
> > ⟨Create an active breakpoint representing the beginning of the paragraph 912⟩;
> > *cur_p* ← *link*(*temp_head*); *auto_breaking* ← *true*;
> > *update_prev_p*;   {glue at beginning is not a legal breakpoint}
> > *first_p* ← *cur_p*;   {to access the first node of paragraph as the first active node has *break_node* = *null*}
> > **while** (*cur_p* ≠ *null*) ∧ (*link*(*active*) ≠ *last_active*) **do** ⟨Call *try_break* if *cur_p* is a legal breakpoint; on the second pass, also try to hyphenate the next word, if *cur_p* is a glue node; then advance *cur_p* to the next node of the paragraph that could possibly be a legal breakpoint 914⟩;
> > **if** *cur_p* = *null* **then** ⟨Try the final line break at the end of the paragraph, and **goto** *done* if the desired breakpoints have been found 921⟩;
> > ⟨Clean up the memory by removing the break nodes 913⟩;
> > **if** ¬*second_pass* **then**
> > > **begin stat if** *tracing_paragraphs* > 0 **then** *print_nl*("@secondpass"); **tats**
> > > *threshold* ← *tolerance*; *second_pass* ← *true*; *final_pass* ← (*emergency_stretch* ≤ 0);
> > > **end**   {if at first you don't succeed, ...}
> > **else begin stat if** *tracing_paragraphs* > 0 **then** *print_nl*("@emergencypass"); **tats**
> > > *background*[2] ← *background*[2] + *emergency_stretch*; *final_pass* ← *true*;
> > > **end**;
> > **end**;
> *done*: **stat if** *tracing_paragraphs* > 0 **then**
> > **begin** *end_diagnostic*(*true*); *normalize_selector*;
> > **end**;
> **tats**
> **if** *do_last_line_fit* **then** ⟨Adjust the final line of the paragraph 1664⟩;

This code is used in section 863.

912. The active node that represents the starting point does not need a corresponding passive node.

define $store\_background(\#) \equiv active\_width[\#] \leftarrow background[\#]$

⟨ Create an active breakpoint representing the beginning of the paragraph 912 ⟩ ≡
  $q \leftarrow get\_node(active\_node\_size);$ $type(q) \leftarrow unhyphenated;$ $fitness(q) \leftarrow decent\_fit;$ $link(q) \leftarrow last\_active;$
  $break\_node(q) \leftarrow null;$ $line\_number(q) \leftarrow prev\_graf + 1;$ $total\_demerits(q) \leftarrow 0;$ $link(active) \leftarrow q;$
  if $do\_last\_line\_fit$ **then** ⟨ Initialize additional fields of the first active node 1656 ⟩;
  $do\_all\_six(store\_background);$
  $passive \leftarrow null;$ $printed\_node \leftarrow temp\_head;$ $pass\_number \leftarrow 0;$ $font\_in\_short\_display \leftarrow null\_font$
This code is used in section 911.

913. ⟨ Clean up the memory by removing the break nodes 913 ⟩ ≡
  $q \leftarrow link(active);$
  while $q \neq last\_active$ **do**
    begin $cur\_p \leftarrow link(q);$
    if $type(q) = delta\_node$ **then** $free\_node(q, delta\_node\_size)$
    else $free\_node(q, active\_node\_size);$
    $q \leftarrow cur\_p;$
    end;
  $q \leftarrow passive;$
  while $q \neq null$ **do**
    begin $cur\_p \leftarrow link(q);$ $free\_node(q, passive\_node\_size);$ $q \leftarrow cur\_p;$
    end
This code is used in sections 863 and 911.

914.   Here is the main switch in the *line_break* routine, where legal breaks are determined. As we move through the hlist, we need to keep the *active_width* array up to date, so that the badness of individual lines is readily calculated by *try_break*. It is convenient to use the short name *act_width* for the component of active width that represents real width as opposed to glue.

> **define** *act_width* ≡ *active_width*[1]   { length from first active node to current node }
> **define** *kern_break* ≡
> > **begin if** ¬*is_char_node*(*link*(*cur_p*)) ∧ *auto_breaking* **then**
> > > **if** *type*(*link*(*cur_p*)) = *glue_node* **then** *try_break*(0, *unhyphenated*);
> > *act_width* ← *act_width* + *width*(*cur_p*);
> > **end**

⟨ Call *try_break* if *cur_p* is a legal breakpoint; on the second pass, also try to hyphenate the next word, if
    cur_p is a glue node; then advance *cur_p* to the next node of the paragraph that could possibly be a
    legal breakpoint 914 ⟩ ≡
  begin if *is_char_node*(*cur_p*) **then**
    ⟨ Advance *cur_p* to the node following the present string of characters 915 ⟩;
  case *type*(*cur_p*) **of**
  hlist_node, *vlist_node*, *rule_node*: *act_width* ← *act_width* + *width*(*cur_p*);
  whatsit_node: ⟨ Advance past a whatsit node in the *line_break* loop 1422 ⟩;
  glue_node: **begin** ⟨ If node *cur_p* is a legal breakpoint, call *try_break*; then update the active widths by
        including the glue in *glue_ptr*(*cur_p*) 916 ⟩;
    if *second_pass* ∧ *auto_breaking* **then** ⟨ Try to hyphenate the following word 943 ⟩;
    end;
  kern_node: **if** *subtype*(*cur_p*) = *explicit* **then** *kern_break*
    else *act_width* ← *act_width* + *width*(*cur_p*);
  ligature_node: **begin** *f* ← *font*(*lig_char*(*cur_p*)); *xtx_ligature_present* ← *true*;
    act_width ← *act_width* + *char_width*(*f*)(*char_info*(*f*)(*character*(*lig_char*(*cur_p*))));
    end;
  disc_node: ⟨ Try to break after a discretionary fragment, then **goto** *done5* 917 ⟩;
  math_node: **begin if** *subtype*(*cur_p*) < *L_code* **then** *auto_breaking* ← *odd*(*subtype*(*cur_p*));
    kern_break;
    end;
  penalty_node: *try_break*(*penalty*(*cur_p*), *unhyphenated*);
  mark_node, *ins_node*, *adjust_node*: *do_nothing*;
  othercases *confusion*("paragraph")
  endcases;
  update_prev_p; *cur_p* ← *link*(*cur_p*);
done5: **end**
This code is used in section 911.

915.   The code that passes over the characters of words in a paragraph is part of TEX's inner loop, so it has been streamlined for speed. We use the fact that '\parfillskip' glue appears at the end of each paragraph; it is therefore unnecessary to check if *link*(*cur_p*) = *null* when *cur_p* is a character node.

⟨ Advance *cur_p* to the node following the present string of characters 915 ⟩ ≡
  begin *update_prev_p*;
  repeat *f* ← *font*(*cur_p*); *act_width* ← *act_width* + *char_width*(*f*)(*char_info*(*f*)(*character*(*cur_p*)));
    cur_p ← *link*(*cur_p*);
  until ¬*is_char_node*(*cur_p*);
  end
This code is used in section 914.

916. When node *cur_p* is a glue node, we look at *prev_p* to see whether or not a breakpoint is legal at *cur_p*, as explained above.

⟨ If node *cur_p* is a legal breakpoint, call *try_break*; then update the active widths by including the glue in *glue_ptr*(*cur_p*) 916 ⟩ ≡

 if *auto_breaking* **then**
  begin if *is_char_node*(*prev_p*) **then** *try_break*(0, *unhyphenated*)
  else if *precedes_break*(*prev_p*) **then** *try_break*(0, *unhyphenated*)
   else if (*type*(*prev_p*) = *kern_node*) ∧ (*subtype*(*prev_p*) ≠ *explicit*) **then** *try_break*(0, *unhyphenated*);
  end;
 check_shrinkage(*glue_ptr*(*cur_p*)); *q* ← *glue_ptr*(*cur_p*); *act_width* ← *act_width* + *width*(*q*);
 active_width[2 + *stretch_order*(*q*)] ← *active_width*[2 + *stretch_order*(*q*)] + *stretch*(*q*);
 active_width[6] ← *active_width*[6] + *shrink*(*q*)

This code is used in section 914.

917. The following code knows that discretionary texts contain only character nodes, kern nodes, box nodes, rule nodes, and ligature nodes.

⟨ Try to break after a discretionary fragment, then **goto** *done5* 917 ⟩ ≡

 begin *s* ← *pre_break*(*cur_p*); *disc_width* ← 0;
 if *s* = *null* **then** *try_break*(*ex_hyphen_penalty*, *hyphenated*)
 else begin repeat ⟨ Add the width of node *s* to *disc_width* 918 ⟩;
  s ← *link*(*s*);
  until *s* = *null*;
  act_width ← *act_width* + *disc_width*; *try_break*(*hyphen_penalty*, *hyphenated*);
  act_width ← *act_width* − *disc_width*;
  end;
 r ← *replace_count*(*cur_p*); *s* ← *link*(*cur_p*);
 while *r* > 0 **do**
  begin ⟨ Add the width of node *s* to *act_width* 919 ⟩;
  decr(*r*); *s* ← *link*(*s*);
  end;
 update_prev_p; *cur_p* ← *s*; **goto** *done5*;
 end

This code is used in section 914.

918. ⟨ Add the width of node *s* to *disc_width* 918 ⟩ ≡

 if *is_char_node*(*s*) **then**
  begin *f* ← *font*(*s*); *disc_width* ← *disc_width* + *char_width*(*f*)(*char_info*(*f*)(*character*(*s*)));
  end
 else case *type*(*s*) **of**
 ligature_node: **begin** *f* ← *font*(*lig_char*(*s*)); *xtx_ligature_present* ← *true*;
  disc_width ← *disc_width* + *char_width*(*f*)(*char_info*(*f*)(*character*(*lig_char*(*s*))));
  end;
 hlist_node, *vlist_node*, *rule_node*, *kern_node*: *disc_width* ← *disc_width* + *width*(*s*);
 whatsit_node: **if** (*is_native_word_subtype*(*s*)) ∨ (*subtype*(*s*) = *glyph_node*) ∨ (*subtype*(*s*) =
   pic_node) ∨ (*subtype*(*s*) = *pdf_node*) **then** *disc_width* ← *disc_width* + *width*(*s*)
  else *confusion*("disc3a");
 othercases *confusion*("disc3")
 endcases

This code is used in section 917.

919. ⟨Add the width of node s to act_width 919⟩ ≡

  if $is\_char\_node(s)$ **then**

    begin $f \leftarrow font(s)$; $act\_width \leftarrow act\_width + char\_width(f)(char\_info(f)(character(s)))$;

    end

  else case $type(s)$ **of**

    $ligature\_node$: **begin** $f \leftarrow font(lig\_char(s))$; $xtx\_ligature\_present \leftarrow true$;

      $act\_width \leftarrow act\_width + char\_width(f)(char\_info(f)(character(lig\_char(s))))$;

      end;

    $hlist\_node, vlist\_node, rule\_node, kern\_node$: $act\_width \leftarrow act\_width + width(s)$;

    $whatsit\_node$: **if** $(is\_native\_word\_subtype(s)) \vee (subtype(s) = glyph\_node) \vee (subtype(s) =$

        $pic\_node) \vee (subtype(s) = pdf\_node)$ **then** $act\_width \leftarrow act\_width + width(s)$

    else $confusion(\texttt{"disc4a"})$;

    othercases $confusion(\texttt{"disc4"})$

    endcases

This code is used in section 917.

920.   The forced line break at the paragraph's end will reduce the list of breakpoints so that all active nodes represent breaks at $cur\_p = null$. On the first pass, we insist on finding an active node that has the correct "looseness." On the final pass, there will be at least one active node, and we will match the desired looseness as well as we can.

    The global variable $best\_bet$ will be set to the active node for the best way to break the paragraph, and a few other variables are used to help determine what is best.

⟨Global variables 13⟩ +≡

$best\_bet$: $pointer$;   {use this passive node and its predecessors}

$fewest\_demerits$: $integer$;   {the demerits associated with $best\_bet$}

$best\_line$: $halfword$;   {line number following the last line of the new paragraph}

$actual\_looseness$: $integer$;   {the difference between $line\_number(best\_bet)$ and the optimum $best\_line$}

$line\_diff$: $integer$;   {the difference between the current line number and the optimum $best\_line$}

921.   ⟨Try the final line break at the end of the paragraph, and **goto** $done$ if the desired breakpoints have been found 921⟩ ≡

  begin $try\_break(eject\_penalty, hyphenated)$;

  if $link(active) \neq last\_active$ **then**

    begin ⟨Find an active node with fewest demerits 922⟩;

    if $looseness = 0$ **then goto** $done$;

    ⟨Find the best active node for the desired looseness 923⟩;

    if $(actual\_looseness = looseness) \vee final\_pass$ **then goto** $done$;

    end;

  end

This code is used in section 911.

922.   ⟨Find an active node with fewest demerits 922⟩ ≡

  $r \leftarrow link(active)$; $fewest\_demerits \leftarrow awful\_bad$;

  repeat if $type(r) \neq delta\_node$ **then**

    if $total\_demerits(r) < fewest\_demerits$ **then**

      begin $fewest\_demerits \leftarrow total\_demerits(r)$; $best\_bet \leftarrow r$;

      end;

    $r \leftarrow link(r)$;

  until $r = last\_active$;

  $best\_line \leftarrow line\_number(best\_bet)$

This code is used in section 921.

923.   The adjustment for a desired looseness is a slightly more complicated version of the loop just considered. Note that if a paragraph is broken into segments by displayed equations, each segment will be subject to the looseness calculation, independently of the other segments.

⟨ Find the best active node for the desired looseness 923 ⟩ ≡
  begin $r \leftarrow link(active)$; $actual\_looseness \leftarrow 0$;
  repeat if $type(r) \neq delta\_node$ **then**
      begin $line\_diff \leftarrow line\_number(r) - best\_line$;
      if $((line\_diff < actual\_looseness) \wedge (looseness \leq line\_diff)) \vee$
            $((line\_diff > actual\_looseness) \wedge (looseness \geq line\_diff))$ **then**
        begin $best\_bet \leftarrow r$; $actual\_looseness \leftarrow line\_diff$; $fewest\_demerits \leftarrow total\_demerits(r)$;
        end
      else if $(line\_diff = actual\_looseness) \wedge (total\_demerits(r) < fewest\_demerits)$ **then**
          begin $best\_bet \leftarrow r$; $fewest\_demerits \leftarrow total\_demerits(r)$;
          end;
      end;
    $r \leftarrow link(r)$;
  until $r = last\_active$;
  $best\_line \leftarrow line\_number(best\_bet)$;
  end

This code is used in section 921.

924.   Once the best sequence of breakpoints has been found (hurray), we call on the procedure *post_line_break* to finish the remainder of the work. (By introducing this subprocedure, we are able to keep *line_break* from getting extremely long.)

⟨ Break the paragraph at the chosen breakpoints, justify the resulting lines to the correct widths, and
      append them to the current vertical list 924 ⟩ ≡
  $post\_line\_break(d)$

This code is used in section 863.

925. The total number of lines that will be set by *post_line_break* is *best_line* − *prev_graf* − 1. The last
breakpoint is specified by *break_node*(*best_bet*), and this passive node points to the other breakpoints via
the *prev_break* links. The finishing-up phase starts by linking the relevant passive nodes in forward order,
changing *prev_break* to *next_break*. (The *next_break* fields actually reside in the same memory space as the
prev_break fields did, but we give them a new name because of their new significance.) Then the lines are
justified, one by one.

> **define** *next_break* ≡ *prev_break*   { new name for *prev_break* after links are reversed }

⟨ Declare subprocedures for *line_break* 874 ⟩ +≡
procedure *post_line_break*(*d* : *boolean*);
  label *done*, *done1*;
  var *q*, *r*, *s*: *pointer*;   { temporary registers for list manipulation }
    p, *k*: *pointer*; *w*: *scaled*; *glue_break*: *boolean*;   { was a break at glue? }
    ptmp: *pointer*; *disc_break*: *boolean*;   { was the current break at a discretionary node? }
    post_disc_break: *boolean*;   { and did it have a nonempty post-break part? }
    cur_width: *scaled*;   { width of line number *cur_line* }
    cur_indent: *scaled*;   { left margin of line number *cur_line* }
    t: *quarterword*;   { used for replacement counts in discretionary nodes }
    pen: *integer*;   { use when calculating penalties between lines }
    cur_line: *halfword*;   { the current line number being justified }
    LR_ptr: *pointer*;   { stack of LR codes }
  begin *LR_ptr* ← *LR_save*;
  ⟨ Reverse the links of the relevant passive nodes, setting *cur_p* to the first breakpoint 926 ⟩;
  cur_line ← *prev_graf* + 1;
  repeat ⟨ Justify the line ending at breakpoint *cur_p*, and append it to the current vertical list, together
        with associated penalties and other insertions 928 ⟩;
    incr(*cur_line*); *cur_p* ← *next_break*(*cur_p*);
    if *cur_p* ≠ *null* **then**
      if ¬*post_disc_break* **then** ⟨ Prune unwanted nodes at the beginning of the next line 927 ⟩;
  until *cur_p* = *null*;
  if (*cur_line* ≠ *best_line*) ∨ (*link*(*temp_head*) ≠ *null*) **then** *confusion*("line␣breaking");
  prev_graf ← *best_line* − 1; *LR_save* ← *LR_ptr*;
  end;

926. The job of reversing links in a list is conveniently regarded as the job of taking items off one stack
and putting them on another. In this case we take them off a stack pointed to by *q* and having *prev_break*
fields; we put them on a stack pointed to by *cur_p* and having *next_break* fields. Node *r* is the passive node
being moved from stack to stack.

⟨ Reverse the links of the relevant passive nodes, setting *cur_p* to the first breakpoint 926 ⟩ ≡
  q ← *break_node*(*best_bet*); *cur_p* ← *null*;
  repeat *r* ← *q*; *q* ← *prev_break*(*q*); *next_break*(*r*) ← *cur_p*; *cur_p* ← *r*;
  until *q* = *null*

This code is used in section 925.

927.   Glue and penalty and kern and math nodes are deleted at the beginning of a line, except in the anomalous case that the node to be deleted is actually one of the chosen breakpoints. Otherwise the pruning done here is designed to match the lookahead computation in *try_break*, where the *break_width* values are computed for non-discretionary breakpoints.

⟨ Prune unwanted nodes at the beginning of the next line 927 ⟩ ≡
   begin $r \leftarrow temp\_head$;
   loop begin $q \leftarrow link(r)$;
     if $q = cur\_break(cur\_p)$ **then goto** *done1*;   { $cur\_break(cur\_p)$ is the next breakpoint }
        { now q cannot be *null* }
     if *is_char_node*(q) **then goto** *done1*;
     if *non_discardable*(q) **then goto** *done1*;
     if $type(q) = kern\_node$ **then**
       if $(subtype(q) \neq explicit) \land (subtype(q) \neq space\_adjustment)$ **then goto** *done1*;
     $r \leftarrow q$;   { now $type(q) = glue\_node$, $kern\_node$, $math\_node$, or $penalty\_node$ }
     if $type(q) = math\_node$ **then**
       if *TeXXeT_en* **then** ⟨ Adjust the LR stack for the *post_line_break* routine 1518 ⟩;
     end;
done1: **if** $r \neq temp\_head$ **then**
    begin $link(r) \leftarrow null$; *flush_node_list*$(link(temp\_head))$; $link(temp\_head) \leftarrow q$;
    end;
  end

This code is used in section 925.

928.   The current line to be justified appears in a horizontal list starting at $link(temp\_head)$ and ending at $cur\_break(cur\_p)$. If $cur\_break(cur\_p)$ is a glue node, we reset the glue to equal the *right_skip* glue; otherwise we append the *right_skip* glue at the right. If $cur\_break(cur\_p)$ is a discretionary node, we modify the list so that the discretionary break is compulsory, and we set *disc_break* to *true*. We also append the *left_skip* glue at the left of the line, unless it is zero.

⟨ Justify the line ending at breakpoint *cur_p*, and append it to the current vertical list, together with
     associated penalties and other insertions 928 ⟩ ≡
  if *TeXXeT_en* **then** ⟨ Insert LR nodes at the beginning of the current line and adjust the LR stack
     based on LR nodes in this line 1517 ⟩;

      begin $k \leftarrow new\_margin\_kern(-w, last\_rightmost\_char, right\_side)$; *link*$(k) \leftarrow link(ptmp)$;
      link$(ptmp) \leftarrow k$;
      if (*ptmp* $= q$) **then** $q \leftarrow link(q)$;
      end;
    end ;   { if q was not a breakpoint at glue and has been reset to *rightskip* then we append *rightskip*
        after q now }
  if ¬*glue_break* **then**
    begin ⟨ Put the \rightskip glue after node q 934 ⟩;
    end;
This code is used in section 928.

930.   ⟨ Change discretionary to compulsory and set *disc_break* $\leftarrow$ *true* 930 ⟩ ≡
  begin $t \leftarrow replace\_count(q)$;
  ⟨ Destroy the t nodes following q, and make r point to the following node 931 ⟩;
  if *post_break*$(q) \neq null$ **then** ⟨ Transplant the post-break list 932 ⟩;
  if *pre_break*$(q) \neq null$ **then** ⟨ Transplant the pre-break list 933 ⟩;
  link$(q) \leftarrow r$; *disc_break* $\leftarrow$ *true*;
  end

This code is used in section 929.

931. ⟨Destroy the t nodes following q, and make r point to the following node 931 ⟩ ≡
  if $t = 0$ **then** $r \leftarrow link(q)$
  else begin $r \leftarrow q$;
    while $t > 1$ **do**
      begin $r \leftarrow link(r)$; $decr(t)$;
      end;
    $s \leftarrow link(r)$; $r \leftarrow link(s)$; $link(s) \leftarrow null$; $flush\_node\_list(link(q))$; $replace\_count(q) \leftarrow 0$;
    end

This code is used in section 930.

932. We move the post-break list from inside node q to the main list by reattaching it just before the present node r, then resetting r.

⟨Transplant the post-break list 932 ⟩ ≡
  begin $s \leftarrow post\_break(q)$;
  while $link(s) \neq null$ **do** $s \leftarrow link(s)$;
  $link(s) \leftarrow r$; $r \leftarrow post\_break(q)$; $post\_break(q) \leftarrow null$; $post\_disc\_break \leftarrow true$;
  end

This code is used in section 930.

933. We move the pre-break list from inside node q to the main list by reattaching it just after the present node q, then resetting q.

⟨Transplant the pre-break list 933 ⟩ ≡
  begin $s \leftarrow pre\_break(q)$; $link(q) \leftarrow s$;
  while $link(s) \neq null$ **do** $s \leftarrow link(s)$;
  $pre\_break(q) \leftarrow null$; $q \leftarrow s$;
  end

This code is used in section 930.

934. ⟨Put the \rightskip glue after node q 934 ⟩ ≡
  $r \leftarrow new\_param\_glue(right\_skip\_code)$; $link(r) \leftarrow link(q)$; $link(q) \leftarrow r$; $q \leftarrow r$
This code is used in section 929.

935. The following code begins with q at the end of the list to be justified. It ends with q at the beginning of that list, and with $link(temp\_head)$ pointing to the remainder of the paragraph, if any.

⟨Put the \leftskip glue at the left and detach this line 935 ⟩ ≡
  $r \leftarrow link(q)$; $link(q) \leftarrow null$; $q \leftarrow link(temp\_head)$; $link(temp\_head) \leftarrow r$;
      { at this point q is the leftmost node; all discardable nodes have been discarded }
  if $XeTeX\_protrude\_chars > 0$ **then**
    begin $p \leftarrow q$; $p \leftarrow find\_protchar\_left(p, false)$;   { no more discardables }
    $w \leftarrow left\_pw(p)$;
    if $w \neq 0$ **then**
      begin $k \leftarrow new\_margin\_kern(-w, last\_leftmost\_char, left\_side)$; $link(k) \leftarrow q$; $q \leftarrow k$;
      end;
    end;
  if $left\_skip \neq zero\_glue$ **then**
    begin $r \leftarrow new\_param\_glue(left\_skip\_code)$; $link(r) \leftarrow q$; $q \leftarrow r$;
    end
This code is used in section 928.

936. ⟨Append the new box to the current vertical list, followed by the list of special nodes taken out of the box by the packager 936⟩ ≡

if *pre_adjust_head* ≠ *pre_adjust_tail* then *append_list*(*pre_adjust_head*)(*pre_adjust_tail*);

pre_adjust_tail ← *null*; *append_to_vlist*(*just_box*);

if *adjust_head* ≠ *adjust_tail* then *append_list*(*adjust_head*)(*adjust_tail*);

adjust_tail ← *null*

This code is used in section 928.

937. Now *q* points to the hlist that represents the current line of the paragraph. We need to compute the appropriate line width, pack the line into a box of this size, and shift the box by the appropriate amount of indentation.

⟨Call the packaging subroutine, setting *just_box* to the justified box 937⟩ ≡

if *cur_line* > *last_special_line* then
   begin *cur_width* ← *second_width*; *cur_indent* ← *second_indent*;
   end
else if *par_shape_ptr* = *null* then
      begin *cur_width* ← *first_width*; *cur_indent* ← *first_indent*;
      end
   else begin *cur_width* ← *mem*[*par_shape_ptr* + 2 * *cur_line*].*sc*;
      cur_indent ← *mem*[*par_shape_ptr* + 2 * *cur_line* − 1].*sc*;
      end;
adjust_tail ← *adjust_head*; *pre_adjust_tail* ← *pre_adjust_head*; *just_box* ← *hpack*(*q*, *cur_width*, *exactly*);
shift_amount(*just_box*) ← *cur_indent*

This code is used in section 928.

938.   Penalties between the lines of a paragraph come from club and widow lines, from the *inter_line_penalty* parameter, and from lines that end at discretionary breaks. Breaking between lines of a two-line paragraph gets both club-line and widow-line penalties. The local variable *pen* will be set to the sum of all relevant penalties for the current line, except that the final line is never penalized.

⟨ Append a penalty node, if a nonzero penalty is appropriate 938 ⟩ ≡
　if *cur_line* + 1 ≠ *best_line* **then**
　　begin $q ← inter\_line\_penalties\_ptr$;
　　if $q ≠ null$ **then**
　　　begin $r ← cur\_line$;
　　　if $r > penalty(q)$ **then** $r ← penalty(q)$;
　　　$pen ← penalty(q + r)$;
　　　end
　　else $pen ← inter\_line\_penalty$;
　　$q ← club\_penalties\_ptr$;
　　if $q ≠ null$ **then**
　　　begin $r ← cur\_line − prev\_graf$;
　　　if $r > penalty(q)$ **then** $r ← penalty(q)$;
　　　$pen ← pen + penalty(q + r)$;
　　　end
　　else if $cur\_line = prev\_graf + 1$ **then** $pen ← pen + club\_penalty$;
　　if d **then** $q ← display\_widow\_penalties\_ptr$
　　else $q ← widow\_penalties\_ptr$;
　　if $q ≠ null$ **then**
　　　begin $r ← best\_line − cur\_line − 1$;
　　　if $r > penalty(q)$ **then** $r ← penalty(q)$;
　　　$pen ← pen + penalty(q + r)$;
　　　end
　　else if $cur\_line + 2 = best\_line$ **then**
　　　　if d **then** $pen ← pen + display\_widow\_penalty$
　　　　else $pen ← pen + widow\_penalty$;
　　if *disc_break* **then** $pen ← pen + broken\_penalty$;
　　if $pen ≠ 0$ **then**
　　　begin $r ← new\_penalty(pen)$; $link(tail) ← r$; $tail ← r$;
　　　end;
　　end

This code is used in section 928.

939.   Pre-hyphenation.   When the line-breaking routine is unable to find a feasible sequence of break-points, it makes a second pass over the paragraph, attempting to hyphenate the hyphenatable words. The goal of hyphenation is to insert discretionary material into the paragraph so that there are more potential places to break.

The general rules for hyphenation are somewhat complex and technical, because we want to be able to hyphenate words that are preceded or followed by punctuation marks, and because we want the rules to work for languages other than English. We also must contend with the fact that hyphens might radically alter the ligature and kerning structure of a word.

A sequence of characters will be considered for hyphenation only if it belongs to a "potentially hyphenatable part" of the current paragraph. This is a sequence of nodes $p_0 p_1 \ldots p_m$ where p_0 is a glue node, $p_1 \ldots p_{m-1}$ are either character or ligature or whatsit or implicit kern or text direction nodes, and p_m is a glue or penalty or insertion or adjust or mark or whatsit or explicit kern node. (Therefore hyphenation is disabled by boxes, math formulas, and discretionary nodes already inserted by the user.) The ligature nodes among $p_1 \ldots p_{m-1}$ are effectively expanded into the original non-ligature characters; the kern nodes and whatsits are ignored. Each character c is now classified as either a nonletter (if $lc\_code(c) = 0$), a lowercase letter (if $lc\_code(c) = c$), or an uppercase letter (otherwise); an uppercase letter is treated as if it were $lc\_code(c)$ for purposes of hyphenation. The characters generated by $p_1 \ldots p_{m-1}$ may begin with nonletters; let c_1 be the first letter that is not in the middle of a ligature. Whatsit nodes preceding c_1 are ignored; a whatsit found after c_1 will be the terminating node p_m. All characters that do not have the same font as c_1 will be treated as nonletters. The *hyphen_char* for that font must be between 0 and 255, otherwise hyphenation will not be attempted. TEX looks ahead for as many consecutive letters $c_1 \ldots c_n$ as possible; however, n must be less than *max_hyphenatable_length* $+ 1$, so a character that would otherwise be $c_{max\_hyphenatable\_length+1}$ is effectively not a letter. Furthermore c_n must not be in the middle of a ligature. In this way we obtain a string of letters $c_1 \ldots c_n$ that are generated by nodes $p_a \ldots p_b$, where $1 \le a \le b+1 \le m$. If $n \ge l\_hyf + r\_hyf$, this string qualifies for hyphenation; however, *uc_hyph* must be positive, if c_1 is uppercase.

The hyphenation process takes place in three stages. First, the candidate sequence $c_1 \ldots c_n$ is found; then potential positions for hyphens are determined by referring to hyphenation tables; and finally, the nodes $p_a \ldots p_b$ are replaced by a new sequence of nodes that includes the discretionary breaks found.

Fortunately, we do not have to do all this calculation very often, because of the way it has been taken out of TEX's inner loop. For example, when the second edition of the author's 700-page book *Seminumerical Algorithms* was typeset by TEX, only about 1.2 hyphenations needed to be tried per paragraph, since the line breaking algorithm needed to use two passes on only about 5 per cent of the paragraphs.

⟨Initialize for hyphenating a paragraph 939⟩ ≡
  begin init if *trie_not_ready* **then** *init_trie*;
  tini
  cur_lang ← *init_cur_lang*; *l_hyf* ← *init_l_hyf*; *r_hyf* ← *init_r_hyf*; *set_hyph_index*;
  end

This code is used in section 911.

940.   The letters $c_1 \ldots c_n$ that are candidates for hyphenation are placed into an array called hc; the number n is placed into hn; pointers to nodes p_{a-1} and p_b in the description above are placed into variables ha and hb; and the font number is placed into hf.

⟨Global variables 13⟩ +≡
hc: **array** $[0 \ldots hyphenatable\_length\_limit + 3]$ **of** $0 \ldots number\_usvs$;   {word to be hyphenated}
        {note that element 0 needs to be a full UnicodeScalar, even though we basically work in UTF16}
hn: $small\_number$;   {the number of positions occupied in hc, 0..64 in TeX}
ha, hb: $pointer$;   {nodes $ha \ldots hb$ should be replaced by the hyphenated result}
hf: $internal\_font\_number$;   {font number of the letters in hc}
hu: **array** $[0 \ldots hyphenatable\_length\_limit + 1]$ **of** $0 \ldots too\_big\_char$;
          {like hc, before conversion to lowercase}
hyf_char: $integer$;   {hyphen character of the relevant font}
$cur\_lang, init\_cur\_lang$: $0 \ldots biggest\_lang$;   {current hyphenation table of interest}
$l\_hyf, r\_hyf, init\_l\_hyf, init\_r\_hyf$: $integer$;   {limits on fragment sizes}
hyf_bchar: $halfword$;   {boundary character after c_n}
max_hyph_char: $integer$;

941.   ⟨Set initial values of key variables 23⟩ +≡
  $max\_hyph\_char \leftarrow too\_big\_lang$;

942.   Hyphenation routines need a few more local variables.

⟨Local variables for line breaking 910⟩ +≡
j: $small\_number$;   {an index into hc or hu}
c: $UnicodeScalar$;   {character being considered for hyphenation}

943.   When the following code is activated, the $line\_break$ procedure is in its second pass, and cur_p points to a glue node.

⟨Try to hyphenate the following word 943⟩ ≡
  begin $prev\_s \leftarrow cur\_p$; $s \leftarrow link(prev\_s)$;
  if $s \neq null$ **then**
    begin ⟨Skip to node ha, or **goto** $done1$ if no hyphenation should be attempted 949⟩;

This code is used in section 943.

953.   Post-hyphenation.   If a hyphen may be inserted between $hc[j]$ and $hc[j+1]$, the hyphenation procedure will set $hyf[j]$ to some small odd number. But before we look at TeX's hyphenation procedure, which is independent of the rest of the line-breaking algorithm, let us consider what we will do with the hyphens it finds, since it is better to work on this part of the program before forgetting what ha and hb, etc., are all about.

⟨ Global variables 13 ⟩ +≡
hyf: **array** $[0 \,.\, hyphenatable\_length\_limit + 1]$ **of** $0 \,.\, 9$;   { odd values indicate discretionary hyphens }
$init\_list$: $pointer$;   { list of punctuation characters preceding the word }
$init\_lig$: $boolean$;   { does $init\_list$ represent a ligature? }
$init\_lft$: $boolean$;   { if so, did the ligature involve a left boundary? }

954.   ⟨ Local variables for hyphenation 954 ⟩ ≡
i, j, l: $0 \,.\, hyphenatable\_length\_limit + 2$;   { indices into hc or hu }
q, r, s: $pointer$;   { temporary registers for list manipulation }
$bchar$: $halfword$;   { boundary character of hyphenated word, or non_char }
See also sections 966, 976, and 983.

This code is used in section 944.

955.   TeX will never insert a hyphen that has fewer than \lefthyphenmin letters before it or fewer than \righthyphenmin after it; hence, a short word has comparatively little chance of being hyphenated. If no hyphens have been found, we can save time by not having to make any changes to the paragraph.

⟨ If no hyphens were found, **return** 955 ⟩ ≡
  for $j \leftarrow l\_hyf$ **to** $hn - r\_hyf$ **do**
    if $odd(hyf[j])$ **then goto** $found1$;
  return;
$found1$:

This code is used in section 944.

956. If hyphens are in fact going to be inserted, TEX first deletes the subsequence of nodes between ha and hb. An attempt is made to preserve the effect that implicit boundary characters and punctuation marks had on ligatures inside the hyphenated word, by storing a left boundary or preceding character in $hu[0]$ and by storing a possible right boundary in $bchar$. We set $j \leftarrow 0$ if $hu[0]$ is to be part of the reconstruction; otherwise $j \leftarrow 1$. The variable s will point to the tail of the current hlist, and q will point to the node following hb, so that things can be hooked up after we reconstitute the hyphenated word.

⟨ Replace nodes $ha \ldots hb$ by a sequence of nodes that includes the discretionary hyphens 956 ⟩ ≡

This code is used in section 956.

958. We must now face the fact that the battle is not over, even though the hyphens have been found: The process of reconstituting a word can be nontrivial because ligatures might change when a hyphen is present. *The TEXbook* discusses the difficulties of the word "difficult", and the discretionary material surrounding a hyphen can be considerably more complex than that. Suppose abcdef is a word in a font for which the only ligatures are bc, cd, de, and ef. If this word permits hyphenation between b and c, the two patterns with and without hyphenation are a b - cd ef and a bc de f. Thus the insertion of a hyphen might cause effects to ripple arbitrarily far into the rest of the word. A further complication arises if additional hyphens appear together with such rippling, e.g., if the word in the example just given could also be hyphenated between c and d; TEX avoids this by simply ignoring the additional hyphens in such weird cases.

    Still further complications arise in the presence of ligatures that do not delete the original characters. When punctuation precedes the word being hyphenated, TEX's method is not perfect under all possible scenarios, because punctuation marks and letters can propagate information back and forth. For example, suppose the original pre-hyphenation pair *a changes to *y via a |=: ligature, which changes to xy via a =:| ligature; if $p_{a-1} = x$ and $p_a = y$, the reconstitution procedure isn't smart enough to obtain xy again. In such cases the font designer should include a ligature that goes from xa to xy.

959.   The processing is facilitated by a subroutine called *reconstitute*. Given a string of characters $x_j \ldots x_n$, there is a smallest index $m \geq j$ such that the "translation" of $x_j \ldots x_n$ by ligatures and kerning has the form $y_1 \ldots y_t$ followed by the translation of $x_{m+1} \ldots x_n$, where $y_1 \ldots y_t$ is some nonempty sequence of character, ligature, and kern nodes. We call $x_j \ldots x_m$ a "cut prefix" of $x_j \ldots x_n$. For example, if $x_1 x_2 x_3 = \mathtt{fly}$, and if the font contains 'fl' as a ligature and a kern between 'fl' and 'y', then $m = 2$, $t = 2$, and y_1 will be a ligature node for 'fl' followed by an appropriate kern node y_2. In the most common case, x_j forms no ligature with x_{j+1} and we simply have $m = j$, $y_1 = x_j$. If $m < n$ we can repeat the procedure on $x_{m+1} \ldots x_n$ until the entire translation has been found.

The *reconstitute* function returns the integer m and puts the nodes $y_1 \ldots y_t$ into a linked list starting at *link*(*hold_head*), getting the input $x_j \ldots x_n$ from the *hu* array. If $x_j = 256$, we consider x_j to be an implicit left boundary character; in this case j must be strictly less than n. There is a parameter *bchar*, which is either 256 or an implicit right boundary character assumed to be present just following x_n. (The value $hu[n+1]$ is never explicitly examined, but the algorithm imagines that *bchar* is there.)

If there exists an index k in the range $j \leq k \leq m$ such that $hyf[k]$ is odd and such that the result of *reconstitute* would have been different if x_{k+1} had been *hchar*, then *reconstitute* sets *hyphen_passed* to the smallest such k. Otherwise it sets *hyphen_passed* to zero.

A special convention is used in the case $j = 0$: Then we assume that the translation of $hu[0]$ appears in a special list of charnodes starting at *init_list*; moreover, if *init_lig* is *true*, then $hu[0]$ will be a ligature character, involving a left boundary if *init_lft* is *true*. This facility is provided for cases when a hyphenated word is preceded by punctuation (like single or double quotes) that might affect the translation of the beginning of the word.

⟨ Global variables 13 ⟩ +≡
hyphen_passed: *small_number*;   { first hyphen in a ligature, if any }

960.   ⟨ Declare the function called *reconstitute* 960 ⟩ ≡

  ⟨ Append a ligature and/or kern to the translation; **goto** *continue* if the stack of inserted ligatures is
      nonempty 964 ⟩;
  reconstitute ← *j*;
  end;

This code is used in section 944.

961.   The reconstitution procedure shares many of the global data structures by which TEX has processed the words before they were hyphenated. There is an implied "cursor" between characters *cur_l* and *cur_r*; these characters will be tested for possible ligature activity. If *ligature_present* then *cur_l* is a ligature character formed from the original characters following *cur_q* in the current translation list. There is a "ligature stack" between the cursor and character $j + 1$, consisting of pseudo-ligature nodes linked together by their *link* fields. This stack is normally empty unless a ligature command has created a new character that will need to be processed later. A pseudo-ligature is a special node having a *character* field that represents a potential ligature and a *lig_ptr* field that points to a *char_node* or is *null*. We have

$$cur\_r = \begin{cases} character(lig\_stack), & \text{if } lig\_stack > null; \\ qi(hu[j+1]), & \text{if } lig\_stack = null \text{ and } j < n; \\ bchar, & \text{if } lig\_stack = null \text{ and } j = n. \end{cases}$$

  end

This code is used in section 963.

966. Okay, we're ready to insert the potential hyphenations that were found. When the following program
is executed, we want to append the word $hu[1 .. hn]$ after node ha, and node q should be appended to
the result. During this process, the variable i will be a temporary index into hu; the variable j will be an
index to our current position in hu; the variable l will be the counterpart of j, in a discretionary branch; the
variable r will point to new nodes being created; and we need a few new local variables:

⟨Local variables for hyphenation 954⟩ +≡
major_tail, *minor_tail*: *pointer*;
    {the end of lists in the main and discretionary branches being reconstructed}
c: *UnicodeScalar*; {character temporarily replaced by a hyphen}
c_loc: 0 .. *hyphenatable_length_limit*; {where that character came from}
r_count: *integer*; {replacement count for discretionary}
hyf_node: *pointer*; {the hyphen, if it exists}

967.   When the following code is performed, $hyf[0]$ and $hyf[hn]$ will be zero.

⟨ Reconstitute nodes for the hyphenated word, inserting discretionary hyphens 967 ⟩ ≡
    repeat $l \leftarrow j;\ \ j \leftarrow reconstitute(j, hn, bchar, qi(hyf\_char)) + 1;$
      if $hyphen\_passed = 0$ **then**
        begin $link(s) \leftarrow link(hold\_head);$
        while $link(s) > null$ **do** $s \leftarrow link(s);$
        if $odd(hyf[j-1])$ **then**
          begin $l \leftarrow j;\ hyphen\_passed \leftarrow j - 1;\ link(hold\_head) \leftarrow null;$
          end;
        end;
      if $hyphen\_passed > 0$ **then** ⟨ Create and append a discretionary node as an alternative to the
           unhyphenated word, and continue to develop both branches until they become equivalent 968 ⟩;
    until $j > hn;$
    $link(s) \leftarrow q$

This code is used in section 956.

968.   In this repeat loop we will insert another discretionary if $hyf[j-1]$ is odd, when both branches of the previous discretionary end at position $j - 1$. Strictly speaking, we aren't justified in doing this, because we don't know that a hyphen after $j - 1$ is truly independent of those branches. But in almost all applications we would rather not lose a potentially valuable hyphenation point. (Consider the word 'difficult', where the letter 'c' is in position j.)

    define $advance\_major\_tail \equiv$
        begin $major\_tail \leftarrow link(major\_tail);\ incr(r\_count);$
        end

⟨ Create and append a discretionary node as an alternative to the unhyphenated word, and continue to
    develop both branches until they become equivalent 968 ⟩ ≡
    repeat $r \leftarrow get\_node(small\_node\_size);\ link(r) \leftarrow link(hold\_head);\ type(r) \leftarrow disc\_node;$
      $major\_tail \leftarrow r;\ r\_count \leftarrow 0;$
      while $link(major\_tail) > null$ **do** $advance\_major\_tail;$
      $i \leftarrow hyphen\_passed;\ hyf[i] \leftarrow 0;$ ⟨ Put the characters $hu[l .. i]$ and a hyphen into $pre\_break(r)$ 969 ⟩;
      ⟨ Put the characters $hu[i+1 ..]$ into $post\_break(r)$, appending to this list and to $major\_tail$ until
          synchronization has been achieved 970 ⟩;
      ⟨ Move pointer s to the end of the current list, and set $replace\_count(r)$ appropriately 972 ⟩;
      $hyphen\_passed \leftarrow j - 1;\ link(hold\_head) \leftarrow null;$
    until $\neg odd(hyf[j-1])$

This code is used in section 967.

969.   The new hyphen might combine with the previous character via ligature or kern. At this point we
have $l - 1 \le i < j$ and $i < hn$.

⟨Put the characters $hu[l \mathinner{.\,.} i]$ and a hyphen into $pre\_break(r)$ 969⟩ ≡
   $minor\_tail \leftarrow null$; $pre\_break(r) \leftarrow null$; $hyf\_node \leftarrow new\_character(hf, hyf\_char)$;
   if $hyf\_node \ne null$ **then**
      begin $incr(i)$; $c \leftarrow hu[i]$; $hu[i] \leftarrow hyf\_char$; $free\_avail(hyf\_node)$;
      end;
   while $l \le i$ **do**
      begin $l \leftarrow reconstitute(l, i, font\_bchar[hf], non\_char) + 1$;
      if $link(hold\_head) > null$ **then**
         begin if $minor\_tail = null$ **then** $pre\_break(r) \leftarrow link(hold\_head)$
         else $link(minor\_tail) \leftarrow link(hold\_head)$;
         $minor\_tail \leftarrow link(hold\_head)$;
         while $link(minor\_tail) > null$ **do** $minor\_tail \leftarrow link(minor\_tail)$;
         end;
      end;
   if $hyf\_node \ne null$ **then**
      begin $hu[i] \leftarrow c$; { restore the character in the hyphen position }
      $l \leftarrow i$; $decr(i)$;
      end

This code is used in section 968.

970.   The synchronization algorithm begins with $l = i + 1 \le j$.

⟨Put the characters $hu[i + 1 \mathinner{.\,.}]$ into $post\_break(r)$, appending to this list and to $major\_tail$ until
       synchronization has been achieved 970⟩ ≡
   $minor\_tail \leftarrow null$; $post\_break(r) \leftarrow null$; $c\_loc \leftarrow 0$;
   if $bchar\_label[hf] \ne non\_address$ **then**   { put left boundary at beginning of new line }
      begin $decr(l)$; $c \leftarrow hu[l]$; $c\_loc \leftarrow l$; $hu[l] \leftarrow max\_hyph\_char$;
      end;
   while $l < j$ **do**
      begin repeat $l \leftarrow reconstitute(l, hn, bchar, non\_char) + 1$;
         if $c\_loc > 0$ **then**
            begin $hu[c\_loc] \leftarrow c$; $c\_loc \leftarrow 0$;
            end;
         if $link(hold\_head) > null$ **then**
            begin if $minor\_tail = null$ **then** $post\_break(r) \leftarrow link(hold\_head)$
            else $link(minor\_tail) \leftarrow link(hold\_head)$;
            $minor\_tail \leftarrow link(hold\_head)$;
            while $link(minor\_tail) > null$ **do** $minor\_tail \leftarrow link(minor\_tail)$;
            end;
      until $l \ge j$;
      while $l > j$ **do** ⟨Append characters of $hu[j \mathinner{.\,.}]$ to $major\_tail$, advancing j 971⟩;
      end

This code is used in section 968.

971.   ⟨Append characters of $hu[j \mathinner{.\,.}]$ to $major\_tail$, advancing j 971⟩ ≡
   begin $j \leftarrow reconstitute(j, hn, bchar, non\_char) + 1$; $link(major\_tail) \leftarrow link(hold\_head)$;
   while $link(major\_tail) > null$ **do** $advance\_major\_tail$;
   end

This code is used in section 970.

972.   Ligature insertion can cause a word to grow exponentially in size. Therefore we must test the size of *r_count* here, even though the hyphenated text was at most *max_hyphenatable_length* characters long.

⟨ Move pointer *s* to the end of the current list, and set *replace_count*(*r*) appropriately 972 ⟩ ≡
    if *r_count* > 127 **then**   { we have to forget the discretionary hyphen }
        begin *link*(*s*) ← *link*(*r*); *link*(*r*) ← *null*; *flush_node_list*(*r*);
        end
    else begin *link*(*s*) ← *r*; *replace_count*(*r*) ← *r_count*;
        end;
    s ← *major_tail*

This code is used in section 968.

973.   Hyphenation.   When a word $hc[1 .. hn]$ has been set up to contain a candidate for hyphenation, TEX first looks to see if it is in the user's exception dictionary. If not, hyphens are inserted based on patterns that appear within the given word, using an algorithm due to Frank M. Liang.

Let's consider Liang's method first, since it is much more interesting than the exception-lookup routine. The algorithm begins by setting $hyf[j]$ to zero for all j, and invalid characters are inserted into $hc[0]$ and $hc[hn+1]$ to serve as delimiters. Then a reasonably fast method is used to see which of a given set of patterns occurs in the word $hc[0 .. (hn+1)]$. Each pattern $p_1 \ldots p_k$ of length k has an associated sequence of $k+1$ numbers $n_0 \ldots n_k$; and if the pattern occurs in $hc[(j+1) .. (j+k)]$, TEX will set $hyf[j+i] \leftarrow \max(hyf[j+i], n_i)$ for $0 \leq i \leq k$. After this has been done for each pattern that occurs, a discretionary hyphen will be inserted between $hc[j]$ and $hc[j+1]$ when $hyf[j]$ is odd, as we have already seen.

The set of patterns $p_1 \ldots p_k$ and associated numbers $n_0 \ldots n_k$ depends, of course, on the language whose words are being hyphenated, and on the degree of hyphenation that is desired. A method for finding appropriate p's and n's, from a given dictionary of words and acceptable hyphenations, is discussed in Liang's Ph.D. thesis (Stanford University, 1983); TEX simply starts with the patterns and works from there.

974.   The patterns are stored in a compact table that is also efficient for retrieval, using a variant of "trie memory" [cf. *The Art of Computer Programming* **3** (1973), 481–505]. We can find each pattern $p_1 \ldots p_k$ by letting z_0 be one greater than the relevant language index and then, for $1 \leq i \leq k$, setting $z_i \leftarrow trie\_link(z_{i-1}) + p_i$; the pattern will be identified by the number z_k. Since all the pattern information is packed together into a single *trie_link* array, it is necessary to prevent confusion between the data from inequivalent patterns, so another table is provided such that $trie\_char(z_i) = p_i$ for all i. There is also a table $trie\_op(z_k)$ to identify the numbers $n_0 \ldots n_k$ associated with $p_1 \ldots p_k$.

Comparatively few different number sequences $n_0 \ldots n_k$ actually occur, since most of the n's are generally zero. Therefore the number sequences are encoded in such a way that $trie\_op(z_k)$ is only one byte long. If $trie\_op(z_k) \neq min\_quarterword$, when $p_1 \ldots p_k$ has matched the letters in $hc[(l-k+1) .. l]$ of language t, we perform all of the required operations for this pattern by carrying out the following little program: Set $v \leftarrow trie\_op(z_k)$. Then set $v \leftarrow v + op\_start[t]$, $hyf[l - hyf\_distance[v]] \leftarrow \max(hyf[l - hyf\_distance[v]], hyf\_num[v])$, and $v \leftarrow hyf\_next[v]$; repeat, if necessary, until $v = min\_quarterword$.

⟨ Types in the outer block 18 ⟩ +≡
  $trie\_pointer = 0 .. trie\_size$;   { an index into *trie* }

975.   define $trie\_link(\#) \equiv trie[\#].rh$ { "downward" link in a trie }
  define $trie\_char(\#) \equiv trie[\#].b1$ { character matched at this trie location }
  define $trie\_op(\#) \equiv trie[\#].b0$ { program for hyphenation at this trie location }

⟨ Global variables 13 ⟩ +≡
trie: **array** [*trie_pointer*] **of** *two_halves*;   { *trie_link*, *trie_char*, *trie_op* }
hyf_distance: **array** [1 .. *trie_op_size*] **of** *small_number*;   { position $k - j$ of n_j }
hyf_num: **array** [1 .. *trie_op_size*] **of** *small_number*;   { value of n_j }
hyf_next: **array** [1 .. *trie_op_size*] **of** *quarterword*;   { continuation code }
op_start: **array** [0 .. *biggest_lang*] **of** 0 .. *trie_op_size*;   { offset for current language }

976.   ⟨ Local variables for hyphenation 954 ⟩ +≡
z: *trie_pointer*;   { an index into *trie* }
v: *integer*;   { an index into *hyf_distance*, etc. }

977.   Assuming that these auxiliary tables have been set up properly, the hyphenation algorithm is quite short.   In the following code we set $hc[hn + 2]$ to the impossible value 256, in order to guarantee that $hc[hn + 3]$ will never be fetched.

⟨Find hyphen locations for the word in hc, or **return** 977⟩ ≡
   for $j \leftarrow 0$ **to** hn **do** $hyf[j] \leftarrow 0$;
  ⟨Look for the word $hc[1 .. hn]$ in the exception table, and **goto** $found$ (with hyf containing the hyphens)
      if an entry is found 984⟩;
  if $trie\_char(cur\_lang + 1) \neq qi(cur\_lang)$ **then return**;   {no patterns for cur_lang}
  $hc[0] \leftarrow 0$; $hc[hn + 1] \leftarrow 0$; $hc[hn + 2] \leftarrow max\_hyph\_char$;   {insert delimiters}
  for $j \leftarrow 0$ **to** $hn - r\_hyf + 1$ **do**
    begin $z \leftarrow trie\_link(cur\_lang + 1) + hc[j]$; $l \leftarrow j$;
    while $hc[l] = qo(trie\_char(z))$ **do**
      begin if $trie\_op(z) \neq min\_quarterword$ **then** ⟨Store maximum values in the hyf table 978⟩;
     $incr(l)$; $z \leftarrow trie\_link(z) + hc[l]$;
     end;
    end;
$found$: **for** $j \leftarrow 0$ **to** $l\_hyf - 1$ **do** $hyf[j] \leftarrow 0$;
  for $j \leftarrow 0$ **to** $r\_hyf - 1$ **do** $hyf[hn - j] \leftarrow 0$

This code is used in section 944.

978.   ⟨Store maximum values in the hyf table 978⟩ ≡
  begin $v \leftarrow trie\_op(z)$;
  repeat $v \leftarrow v + op\_start[cur\_lang]$; $i \leftarrow l - hyf\_distance[v]$;
    if $hyf\_num[v] > hyf[i]$ **then** $hyf[i] \leftarrow hyf\_num[v]$;
    $v \leftarrow hyf\_next[v]$;
  until $v = min\_quarterword$;
  end

This code is used in section 977.

979.   The exception table that is built by TEX's \hyphenation primitive is organized as an ordered hash table [cf. Amble and Knuth, *The Computer Journal* **17** (1974), 135–142] using linear probing. If α and β are words, we will say that $\alpha < \beta$ if $|\alpha| < |\beta|$ or if $|\alpha| = |\beta|$ and α is lexicographically smaller than β. (The notation $|\alpha|$ stands for the length of α.) The idea of ordered hashing is to arrange the table so that a given word α can be sought by computing a hash address $h = h(\alpha)$ and then looking in table positions h, $h - 1$, ..., until encountering the first word $\leq \alpha$. If this word is different from α, we can conclude that α is not in the table.

The words in the table point to lists in mem that specify hyphen positions in their $info$ fields. The list for $c_1 \ldots c_n$ contains the number k if the word $c_1 \ldots c_n$ has a discretionary hyphen between c_k and c_{k+1}.

⟨Types in the outer block 18⟩ +≡
  $hyph\_pointer = 0 .. hyph\_size$;   {an index into the ordered hash table}

980.   ⟨Global variables 13⟩ +≡
$hyph\_word$: **array** [$hyph\_pointer$] **of** str_number;   {exception words}
$hyph\_list$: **array** [$hyph\_pointer$] **of** $pointer$;   {lists of hyphen positions}
$hyph\_count$: $hyph\_pointer$;   {the number of words in the exception dictionary}

981.   ⟨Local variables for initialization 19⟩ +≡
z: $hyph\_pointer$;   {runs through the exception dictionary}

982. ⟨Set initial values of key variables 23⟩ +≡
  for $z \leftarrow 0$ **to** $hyph\_size$ **do**
    begin $hyph\_word[z] \leftarrow 0$; $hyph\_list[z] \leftarrow null$;
    end;
  $hyph\_count \leftarrow 0$;

983.   The algorithm for exception lookup is quite simple, as soon as we have a few more local variables to work with.

⟨Local variables for hyphenation 954⟩ +≡
h: $hyph\_pointer$;   { an index into $hyph\_word$ and $hyph\_list$ }
k: str_number;   { an index into str_start }
u: $pool\_pointer$;   { an index into str_pool }

984.   First we compute the hash code h, then we search until we either find the word or we don't. Words from different languages are kept separate by appending the language code to the string.

⟨Look for the word $hc[1 . . hn]$ in the exception table, and **goto** $found$ (with hyf containing the hyphens) if
      an entry is found 984⟩ ≡
  $h \leftarrow hc[1]$; $incr(hn)$; $hc[hn] \leftarrow cur\_lang$;
  for $j \leftarrow 2$ **to** hn **do** $h \leftarrow (h + h + hc[j]) \bmod hyph\_size$;
  loop begin ⟨If the string $hyph\_word[h]$ is less than $hc[1 . . hn]$, **goto** not_found; but if the two strings
          are equal, set hyf to the hyphen positions and **goto** $found$ 985⟩;
    if $h > 0$ **then** $decr(h)$ **else** $h \leftarrow hyph\_size$;
    end;
not_found: $decr(hn)$
This code is used in section 977.

985.   ⟨If the string $hyph\_word[h]$ is less than $hc[1 . . hn]$, **goto** not_found; but if the two strings are equal,
      set hyf to the hyphen positions and **goto** $found$ 985⟩ ≡
  $k \leftarrow hyph\_word[h]$;
  if $k = 0$ **then goto** not_found;
  if $length(k) < hn$ **then goto** not_found;
  if $length(k) = hn$ **then**
    begin $j \leftarrow 1$; $u \leftarrow str\_start\_macro(k)$;
    repeat if $so(str\_pool[u]) < hc[j]$ **then goto** not_found;
      if $so(str\_pool[u]) > hc[j]$ **then goto** $done$;
      $incr(j)$; $incr(u)$;
    until $j > hn$;
    ⟨Insert hyphens as specified in $hyph\_list[h]$ 986⟩;
    $decr(hn)$; **goto** $found$;
    end;
$done$:
This code is used in section 984.

986.   ⟨Insert hyphens as specified in $hyph\_list[h]$ 986⟩ ≡
  $s \leftarrow hyph\_list[h]$;
  while $s \neq null$ **do**
    begin $hyf[info(s)] \leftarrow 1$; $s \leftarrow link(s)$;
    end
This code is used in section 985.

987.   ⟨Search *hyph_list* for pointers to p 987⟩ ≡
  for $q \leftarrow 0$ **to** *hyph_size* **do**
    begin if *hyph_list*$[q] = p$ **then**
      begin *print_nl*("HYPH("); *print_int*(q); *print_char*(")");
      end;
    end

This code is used in section 197.

988.   We have now completed the hyphenation routine, so the *line_break* procedure is finished at last. Since the hyphenation exception table is fresh in our minds, it's a good time to deal with the routine that adds new entries to it.

   When T$_E$X has scanned '\hyphenation', it calls on a procedure named *new_hyph_exceptions* to do the right thing.

  define *set_cur_lang* ≡
            if *language* ≤ 0 **then** *cur_lang* ← 0

996. Initializing the hyphenation tables.   The trie for TeX's hyphenation algorithm is built from a sequence of patterns following a `\patterns` specification. Such a specification is allowed only in INITEX, since the extra memory for auxiliary tables and for the initialization program itself would only clutter up the production version of TeX with a lot of deadwood.

The first step is to build a trie that is linked, instead of packed into sequential storage, so that insertions are readily made. After all patterns have been processed, INITEX compresses the linked trie by identifying common subtries. Finally the trie is packed into the efficient sequential form that the hyphenation algorithm actually uses.

⟨ Declare subprocedures for *line_break* 874 ⟩ +≡
  init ⟨ Declare procedures for preprocessing hyphenation patterns 998 ⟩
  tini

997.   Before we discuss trie building in detail, let's consider the simpler problem of creating the *hyf_distance*, *hyf_num*, and *hyf_next* arrays.

Suppose, for example, that TeX reads the pattern '`ab2cde1`'. This is a pattern of length 5, with $n_0 \ldots n_5 = 002001$ in the notation above. We want the corresponding *trie_op* code v to have $hyf\_distance[v] = 3$, $hyf\_num[v] = 2$, and $hyf\_next[v] = v'$, where the auxiliary *trie_op* code v' has $hyf\_distance[v'] = 0$, $hyf\_num[v'] = 1$, and $hyf\_next[v'] = min\_quarterword$.

TeX computes an appropriate value v with the *new_trie_op* subroutine below, by setting

$$v' \leftarrow new\_trie\_op(0, 1, min\_quarterword), \qquad v \leftarrow new\_trie\_op(3, 2, v').$$

This subroutine looks up its three parameters in a special hash table, assigning a new value only if these three have not appeared before for the current language.

The hash table is called *trie_op_hash*, and the number of entries it contains is *trie_op_ptr*.

⟨ Global variables 13 ⟩ +≡
  init *trie_op_hash*: **array** $[-trie\_op\_size \, .. \, trie\_op\_size]$ **of** $0 \, .. \, trie\_op\_size$;
        { trie op codes for quadruples }
trie_used: **array** $[ASCII\_code]$ **of** *quarterword*; { largest opcode used so far for this language }
trie_op_lang: **array** $[1 \, .. \, trie\_op\_size]$ **of** $0 \, .. \, biggest\_lang$; { language part of a hashed quadruple }
trie_op_val: **array** $[1 \, .. \, trie\_op\_size]$ **of** *quarterword*; { opcode corresponding to a hashed quadruple }
trie_op_ptr: $0 \, .. \, trie\_op\_size$; { number of stored ops so far }
  tini

998.   It's tempting to remove the *overflow* stops in the following procedure; *new_trie_op* could return *min_quarterword* (thereby simply ignoring part of a hyphenation pattern) instead of aborting the job. However, that would lead to different hyphenation results on different installations of TEX using the same patterns. The *overflow* stops are necessary for portability of patterns.

⟨ Declare procedures for preprocessing hyphenation patterns 998 ⟩ ≡
function *new_trie_op*(*d, n* : *small_number*; *v* : *quarterword*): *quarterword*;
  label *exit*;
  var *h*: −*trie_op_size* .. *trie_op_size*; { trial hash location }
    u: *quarterword*; { trial op code }
    l: 0 .. *trie_op_size*; { pointer to stored data }

      trie_op_hash[*j*] ← *trie_op_hash*[*k*]; *trie_op_hash*[*k*] ← *k*;
      end
This code is used in section 1006.

1000.   Before we forget how to initialize the data structures that have been mentioned so far, let's write down the code that gets them started.

⟨Initialize table entries (done by INITEX only) 189⟩ +≡
  for $k \leftarrow -trie\_op\_size$ **to** $trie\_op\_size$ **do** $trie\_op\_hash[k] \leftarrow 0$;
  for $k \leftarrow 0$ **to** 255 **do** $trie\_used[k] \leftarrow min\_quarterword$;
  $trie\_op\_ptr \leftarrow 0$;

1001.   The linked trie that is used to preprocess hyphenation patterns appears in several global arrays. Each node represents an instruction of the form "if you see character c, then perform operation o, move to the next character, and go to node l; otherwise go to node r." The four quantities c, o, l, and r are stored in four arrays $trie\_c$, $trie\_o$, $trie\_l$, and $trie\_r$. The root of the trie is $trie\_l[0]$, and the number of nodes is $trie\_ptr$. Null trie pointers are represented by zero. To initialize the trie, we simply set $trie\_l[0]$ and $trie\_ptr$ to zero. We also set $trie\_c[0]$ to some arbitrary value, since the algorithm may access it.

The algorithms maintain the condition

$$trie\_c[trie\_r[z]] > trie\_c[z] \qquad \text{whenever } z \neq 0 \text{ and } trie\_r[z] \neq 0;$$

in other words, sibling nodes are ordered by their c fields.

  define $trie\_root \equiv trie\_l[0]$ { root of the linked trie }

⟨Global variables 13⟩ +≡
  init $trie\_c$: **packed array** $[trie\_pointer]$ **of** $packed\_ASCII\_code$;   { characters to match }
  $trie\_o$: **packed array** $[trie\_pointer]$ **of** $quarterword$;   { operations to perform }
  $trie\_l$: **packed array** $[trie\_pointer]$ **of** $trie\_pointer$;   { left subtrie links }
  $trie\_r$: **packed array** $[trie\_pointer]$ **of** $trie\_pointer$;   { right subtrie links }
  $trie\_ptr$: $trie\_pointer$;   { the number of nodes in the trie }
  $trie\_hash$: **packed array** $[trie\_pointer]$ **of** $trie\_pointer$;   { used to identify equivalent subtries }
  tini

1002.   Let us suppose that a linked trie has already been constructed. Experience shows that we can often reduce its size by recognizing common subtries; therefore another hash table is introduced for this purpose, somewhat similar to $trie\_op\_hash$. The new hash table will be initialized to zero.

The function $trie\_node(p)$ returns p if p is distinct from other nodes that it has seen, otherwise it returns the number of the first equivalent node that it has seen.

Notice that we might make subtries equivalent even if they correspond to patterns for different languages, in which the trie ops might mean quite different things. That's perfectly all right.

⟨Declare procedures for preprocessing hyphenation patterns 998⟩ +≡
function $trie\_node(p : trie\_pointer)$: $trie\_pointer$;   { converts to a canonical form }
  label $exit$;
  var h: $trie\_pointer$;   { trial hash location }
    q: $trie\_pointer$;   { trial trie node }
  begin $h \leftarrow abs(trie\_c[p] + 1009 * trie\_o[p] + 2718 * trie\_l[p] + 3142 * trie\_r[p])$ **mod** $trie\_size$;
  loop begin $q \leftarrow trie\_hash[h]$;
    if $q = 0$ **then**
      begin $trie\_hash[h] \leftarrow p$; $trie\_node \leftarrow p$; **return**;
      end;
    if $(trie\_c[q] = trie\_c[p]) \wedge (trie\_o[q] = trie\_o[p]) \wedge (trie\_l[q] = trie\_l[p]) \wedge (trie\_r[q] = trie\_r[p])$ **then**
      begin $trie\_node \leftarrow q$; **return**;
      end;
    if $h > 0$ **then** $decr(h)$ **else** $h \leftarrow trie\_size$;
    end;
$exit$: **end**;

1003. A neat recursive procedure is now able to compress a trie by traversing it and applying *trie_node* to its nodes in "bottom up" fashion. We will compress the entire trie by clearing *trie_hash* to zero and then saying '*trie_root* ← *compress_trie*(*trie_root*)'.

⟨Declare procedures for preprocessing hyphenation patterns 998⟩ +≡
function *compress_trie*(*p* : *trie_pointer*): *trie_pointer*;
  begin if *p* = 0 **then** *compress_trie* ← 0
  else begin *trie_l*[*p*] ← *compress_trie*(*trie_l*[*p*]); *trie_r*[*p*] ← *compress_trie*(*trie_r*[*p*]);
    compress_trie ← *trie_node*(*p*);
    end;
  end;

1004. The compressed trie will be packed into the *trie* array using a "top-down first-fit" procedure. This is a little tricky, so the reader should pay close attention: The *trie_hash* array is cleared to zero again and renamed *trie_ref* for this phase of the operation; later on, *trie_ref*[*p*] will be nonzero only if the linked trie node *p* is the smallest character in a family and if the characters *c* of that family have been allocated to locations *trie_ref*[*p*] + *c* in the *trie* array. Locations of *trie* that are in use will have *trie_link* = 0, while the unused holes in *trie* will be doubly linked with *trie_link* pointing to the next larger vacant location and *trie_back* pointing to the next smaller one. This double linking will have been carried out only as far as *trie_max*, where *trie_max* is the largest index of *trie* that will be needed. To save time at the low end of the trie, we maintain array entries *trie_min*[*c*] pointing to the smallest hole that is greater than *c*. Another array *trie_taken* tells whether or not a given location is equal to *trie_ref*[*p*] for some *p*; this array is used to ensure that distinct nodes in the compressed trie will have distinct *trie_ref* entries.

  define *trie_ref* ≡ *trie_hash*   {where linked trie families go into *trie* }
  define *trie_back*(#) ≡ *trie*[#].*lh*   {backward links in *trie* holes }

⟨Global variables 13⟩ +≡
  init *trie_taken*: **packed array** [1 .. *trie_size*] **of** *boolean*;   {does a family start here? }
  trie_min: **array** [*ASCII_code*] **of** *trie_pointer*;   {the first possible slot for each character }
  trie_max: *trie_pointer*;   {largest location used in *trie* }
  trie_not_ready: *boolean*;   {is the trie still in linked form? }
  tini

1005. Each time \patterns appears, it contributes further patterns to the future trie, which will be built only when hyphenation is attempted or when a format file is dumped. The boolean variable *trie_not_ready* will change to *false* when the trie is compressed; this will disable further patterns.

⟨Initialize table entries (done by INITEX only) 189⟩ +≡
  trie_not_ready ← *true*; *trie_root* ← 0; *trie_c*[0] ← *si*(0); *trie_ptr* ← 0;

1006. Here is how the trie-compression data structures are initialized. If storage is tight, it would be possible to overlap *trie_op_hash*, *trie_op_lang*, and *trie_op_val* with *trie*, *trie_hash*, and *trie_taken*, because we finish with the former just before we need the latter.

⟨Get ready to compress the trie 1006⟩ ≡
  ⟨Sort the hyphenation op tables into proper order 999⟩;
  for *p* ← 0 **to** *trie_size* **do** *trie_hash*[*p*] ← 0;
  hyph_root ← *compress_trie*(*hyph_root*); *trie_root* ← *compress_trie*(*trie_root*);
      {identify equivalent subtries }
  for *p* ← 0 **to** *trie_ptr* **do** *trie_ref*[*p*] ← 0;
  for *p* ← 0 **to** *biggest_char* **do** *trie_min*[*p*] ← *p* + 1;
  trie_link(0) ← 1; *trie_max* ← 0
This code is used in section 1020.

1007. The *first_fit* procedure finds the smallest hole z in *trie* such that a trie family starting at a given node p will fit into vacant positions starting at z. If $c = trie\_c[p]$, this means that location $z - c$ must not already be taken by some other family, and that $z - c + c'$ must be vacant for all characters c' in the family. The procedure sets *trie_ref*$[p]$ to $z - c$ when the first fit has been found.

⟨ Declare procedures for preprocessing hyphenation patterns 998 ⟩ +≡
procedure *first_fit*(p : *trie_pointer*);   { packs a family into *trie* }
  label *not_found*, *found*;
  var h: *trie_pointer*;   { candidate for *trie_ref*$[p]$ }
    z: *trie_pointer*;   { runs through holes }
    q: *trie_pointer*;   { runs through the family starting at p }
    c: *ASCII_code*;   { smallest character in the family }
    l, r: *trie_pointer*;   { left and right neighbors }
    ll: $1 .. too\_big\_char$;   { upper limit of *trie_min* updating }
  begin $c \leftarrow so(trie\_c[p])$; $z \leftarrow trie\_min[c]$;   { get the first conceivably good hole }
  loop begin $h \leftarrow z - c$;
    ⟨ Ensure that $trie\_max \geq h + max\_hyph\_char$ 1008 ⟩;
    if *trie_taken*$[h]$ **then goto** *not_found*;
    ⟨ If all characters of the family fit relative to h, then **goto** *found*, otherwise **goto** *not_found* 1009 ⟩;
  not_found: $z \leftarrow trie\_link(z)$;   { move to the next hole }
    end;
found: ⟨ Pack the family into *trie* relative to h 1010 ⟩;
  end;

1008. By making sure that *trie_max* is at least $h + max\_hyph\_char$, we can be sure that $trie\_max > z$, since $h = z - c$. It follows that location *trie_max* will never be occupied in *trie*, and we will have $trie\_max \geq trie\_link(z)$.

⟨ Ensure that $trie\_max \geq h + max\_hyph\_char$ 1008 ⟩ ≡
  if $trie\_max < h + max\_hyph\_char$ **then**
    begin if $trie\_size \leq h + max\_hyph\_char$ **then** *overflow*("pattern␣memory", *trie_size*);
    repeat *incr*(*trie_max*); *trie_taken*[*trie_max*] ← *false*; *trie_link*(*trie_max*) ← *trie_max* + 1;
      trie_back(*trie_max*) ← *trie_max* − 1;
    until $trie\_max = h + max\_hyph\_char$;
    end

This code is used in section 1007.

1009. ⟨ If all characters of the family fit relative to h, then **goto** *found*, otherwise **goto** *not_found* 1009 ⟩ ≡
  $q \leftarrow trie\_r[p]$;
  while $q > 0$ **do**
    begin if $trie\_link(h + so(trie\_c[q])) = 0$ **then goto** *not_found*;
    $q \leftarrow trie\_r[q]$;
    end;
  goto *found*

This code is used in section 1007.

1010. ⟨Pack the family into *trie* relative to *h* 1010⟩ ≡
  trie_taken[*h*] ← *true*; *trie_ref*[*p*] ← *h*; *q* ← *p*;
  repeat *z* ← *h* + *so*(*trie_c*[*q*]); *l* ← *trie_back*(*z*); *r* ← *trie_link*(*z*); *trie_back*(*r*) ← *l*; *trie_link*(*l*) ← *r*;
    trie_link(*z*) ← 0;
    if *l* < *max_hyph_char* **then**
      begin if *z* < *max_hyph_char* **then** *ll* ← *z* **else** *ll* ← *max_hyph_char*;
      repeat *trie_min*[*l*] ← *r*; *incr*(*l*);
      until *l* = *ll*;
      end;
    q ← *trie_r*[*q*];
  until *q* = 0
This code is used in section 1007.

1011. To pack the entire linked trie, we use the following recursive procedure.

⟨Declare procedures for preprocessing hyphenation patterns 998⟩ +≡
procedure *trie_pack*(*p* : *trie_pointer*);   {pack subtries of a family}
  var *q*: *trie_pointer*;   {a local variable that need not be saved on recursive calls}
  begin repeat *q* ← *trie_l*[*p*];
    if (*q* > 0) ∧ (*trie_ref*[*q*] = 0) **then**
      begin *first_fit*(*q*); *trie_pack*(*q*);
      end;
    p ← *trie_r*[*p*];
  until *p* = 0;
  end;

1012. When the whole trie has been allocated into the sequential table, we must go through it once again so that *trie* contains the correct information. Null pointers in the linked trie will be represented by the value 0, which properly implements an "empty" family.

⟨Move the data into *trie* 1012⟩ ≡
  h.rh ← 0; *h.b0* ← *min_quarterword*; *h.b1* ← *min_quarterword*;
      {*trie_link* ← 0, *trie_op* ← *min_quarterword*, *trie_char* ← *qi*(0)}
  if *trie_max* = 0 **then**   {no patterns were given}
    begin for *r* ← 0 **to** 256 **do** *trie*[*r*] ← *h*;
    trie_max ← 256;
    end
  else begin if *hyph_root* > 0 **then** *trie_fix*(*hyph_root*);
    if *trie_root* > 0 **then** *trie_fix*(*trie_root*);   {this fixes the non-holes in *trie*}
    r ← 0;   {now we will zero out all the holes}
    repeat *s* ← *trie_link*(*r*); *trie*[*r*] ← *h*; *r* ← *s*;
    until *r* > *trie_max*;
    end;
  trie_char(0) ← *qi*("?");   {make *trie_char*(*c*) ≠ *c* for all *c*}
This code is used in section 1020.

1013. The fixing-up procedure is, of course, recursive. Since the linked trie usually has overlapping subtries, the same data may be moved several times; but that causes no harm, and at most as much work is done as it took to build the uncompressed trie.

⟨Declare procedures for preprocessing hyphenation patterns 998⟩ +≡

procedure *trie_fix*(*p* : *trie_pointer*);   {moves *p* and its siblings into *trie*}
  var *q*: *trie_pointer*;   {a local variable that need not be saved on recursive calls}
    c: *ASCII_code*;   {another one that need not be saved}
    z: *trie_pointer*;   {*trie* reference; this local variable must be saved}
  begin *z* ← *trie_ref*[*p*];
  repeat *q* ← *trie_l*[*p*]; *c* ← *so*(*trie_c*[*p*]); *trie_link*(*z* + *c*) ← *trie_ref*[*q*]; *trie_char*(*z* + *c*) ← *qi*(*c*);
    trie_op(*z* + *c*) ← *trie_o*[*p*];
    if *q* > 0 **then** *trie_fix*(*q*);
    p ← *trie_r*[*p*];
  until *p* = 0;
  end;

1014. Now let's go back to the easier problem, of building the linked trie. When INITEX has scanned the '\patterns' control sequence, it calls on *new_patterns* to do the right thing.

⟨Declare procedures for preprocessing hyphenation patterns 998⟩ +≡

procedure *new_patterns*;   {initializes the hyphenation pattern data}
  label *done*, *done1*;
  var *k*, *l*: 0 . . *hyphenatable_length_limit* + 1;
      {indices into *hc* and *hyf*; not always in *small_number* range}
    digit_sensed: *boolean*;   {should the next digit be treated as a letter?}
    v: *quarterword*;   {trie op code}
    p, *q*: *trie_pointer*;   {nodes of trie traversed during insertion}
    first_child: *boolean*;   {is *p* = *trie_l*[*q*]?}
    c: *ASCII_code*;   {character being inserted}
  begin if *trie_not_ready* **then**
    begin *set_cur_lang*; *scan_left_brace*;   {a left brace must follow \patterns}
    ⟨Enter all of the patterns into a linked trie, until coming to a right brace 1015⟩;
    if *saving_hyph_codes* > 0 **then** ⟨Store hyphenation codes for current language 1666⟩;
    end
  else begin *print_err*("Too␣late␣for␣"); *print_esc*("patterns");
    help1("All␣patterns␣must␣be␣given␣before␣typesetting␣begins."); *error*;
    link(*garbage*) ← *scan_toks*(*false*, *false*); *flush_list*(*def_ref*);
    end;
  end;

1015.   Novices are not supposed to be using \patterns, so the error messages are terse. (Note that all error messages appear in TEX's string pool, even if they are used only by INITEX.)

⟨ Enter all of the patterns into a linked trie, until coming to a right brace 1015 ⟩ ≡
    $k \leftarrow 0$; $hyf[0] \leftarrow 0$; $digit\_sensed \leftarrow false$;
  loop begin get_x_token;
    case cur_cmd **of**
    $letter, other\_char$: ⟨ Append a new letter or a hyphen level 1016 ⟩;
    $spacer, right\_brace$: **begin if** $k > 0$ **then** ⟨ Insert a new pattern into the linked trie 1017 ⟩;
      if $cur\_cmd = right\_brace$ **then goto** $done$;
      $k \leftarrow 0$; $hyf[0] \leftarrow 0$; $digit\_sensed \leftarrow false$;
      end;
    othercases begin $print\_err("Bad_{\sqcup}")$; $print\_esc("patterns")$; $help1("(See_{\sqcup}Appendix_{\sqcup}H.)")$; $error$;
      end
    endcases;
    end;

    end;
$done1$:

This code is used in section 1017.

1020.   Finally we put everything together: Here is how the trie gets to its final, efficient form. The following packing routine is rigged so that the root of the linked tree gets mapped into location 1 of *trie*, as required by the hyphenation algorithm. This happens because the first call of *first_fit* will "take" location 1.

⟨ Declare procedures for preprocessing hyphenation patterns 998 ⟩ +≡
procedure *init_trie*;
  var *p*: *trie_pointer*;   { pointer for initialization }
    j, k, t: *integer*;   { all-purpose registers for initialization }
    r, s: *trie_pointer*;   { used to clean up the packed *trie* }
    h: *two_halves*;   { template used to zero out *trie*'s holes }
  begin *incr*(*max_hyph_char*); ⟨ Get ready to compress the trie 1006 ⟩;
  if *trie_root* ≠ 0 **then**
    begin *first_fit*(*trie_root*); *trie_pack*(*trie_root*);
    end;
  if *hyph_root* ≠ 0 **then** ⟨ Pack all stored *hyph_codes* 1668 ⟩;
  ⟨ Move the data into *trie* 1012 ⟩;
  trie_not_ready ← *false*;
  end;

1021. Breaking vertical lists into pages.   The *vsplit* procedure, which implements TEX's \vsplit operation, is considerably simpler than *line_break* because it doesn't have to worry about hyphenation, and because its mission is to discover a single break instead of an optimum sequence of breakpoints. But before we get into the details of *vsplit*, we need to consider a few more basic things.

1022.   A subroutine called *prune_page_top* takes a pointer to a vlist and returns a pointer to a modified vlist in which all glue, kern, and penalty nodes have been deleted before the first box or rule node. However, the first box or rule is actually preceded by a newly created glue node designed so that the topmost baseline will be at distance *split_top_skip* from the top, whenever this is possible without backspacing.

When the second argument *s* is *false* the deleted nodes are destroyed, otherwise they are collected in a list starting at *split_disc*.

In this routine and those that follow, we make use of the fact that a vertical list contains no character nodes, hence the *type* field exists for each node in the list.

function *prune_page_top*(*p* : *pointer*; *s* : *boolean*): *pointer*;   { adjust top after page break }
  var *prev_p*: *pointer*;   { lags one step behind *p* }
    q, r: *pointer*;   { temporary variables for list manipulation }
  begin *prev_p* ← *temp_head*; *link*(*temp_head*) ← *p*;
  while *p* ≠ *null* **do**
    case *type*(*p*) **of**
    hlist_node, *vlist_node*, *rule_node*: ⟨Insert glue for *split_top_skip* and set *p* ← *null* 1023⟩;
    whatsit_node, *mark_node*, *ins_node*: **begin** *prev_p* ← *p*; *p* ← *link*(*prev_p*);
      end;
    glue_node, *kern_node*, *penalty_node*: **begin** *q* ← *p*; *p* ← *link*(*q*); *link*(*q*) ← *null*; *link*(*prev_p*) ← *p*;
      if *s* **then**
        begin if *split_disc* = *null* **then** *split_disc* ← *q* **else** *link*(*r*) ← *q*;
        r ← *q*;
        end
      else *flush_node_list*(*q*);
      end;
    othercases *confusion*("pruning")
    endcases;
  prune_page_top ← *link*(*temp_head*);
  end;

1023.   ⟨Insert glue for *split_top_skip* and set *p* ← *null* 1023⟩ ≡
  begin *q* ← *new_skip_param*(*split_top_skip_code*); *link*(*prev_p*) ← *q*; *link*(*q*) ← *p*;
    { now *temp_ptr* = *glue_ptr*(*q*) }
  if *XeTeX_upwards* **then**
    begin if *width*(*temp_ptr*) > *depth*(*p*) **then** *width*(*temp_ptr*) ← *width*(*temp_ptr*) − *depth*(*p*)
    else *width*(*temp_ptr*) ← 0;
    end
  else begin if *width*(*temp_ptr*) > *height*(*p*) **then** *width*(*temp_ptr*) ← *width*(*temp_ptr*) − *height*(*p*)
    else *width*(*temp_ptr*) ← 0;
    end;
  p ← *null*;
  end

This code is used in section 1022.

1024.   The next subroutine finds the best place to break a given vertical list so as to obtain a box of
height h, with maximum depth d. A pointer to the beginning of the vertical list is given, and a pointer to
the optimum breakpoint is returned. The list is effectively followed by a forced break, i.e., a penalty node
with the *eject_penalty*; if the best break occurs at this artificial node, the value *null* is returned.

An array of six *scaled* distances is used to keep track of the height from the beginning of the list to the
current place, just as in *line_break*. In fact, we use one of the same arrays, only changing its name to reflect
its new significance.

> **define** *active_height* ≡ *active_width*   { new name for the six distance variables }
> **define** *cur_height* ≡ *active_height*[1]   { the natural height }
> **define** *set_height_zero*(#) ≡ *active_height*[#] ← 0   { initialize the height to zero }
>
> **define** *update_heights* = 90   { go here to record glue in the *active_height* table }

function *vert_break*(p : *pointer*; h, d : *scaled*): *pointer*;   { finds optimum page break }
  label *done*, *not_found*, *update_heights*;
  var *prev_p*: *pointer*;   { if p is a glue node, *type*(*prev_p*) determines whether p is a legal breakpoint }
    q, r: *pointer*;   { glue specifications }
    pi: *integer*;   { penalty value }
    b: *integer*;   { badness at a trial breakpoint }
    least_cost: *integer*;   { the smallest badness plus penalties found so far }
    best_place: *pointer*;   { the most recent break that leads to *least_cost* }
    prev_dp: *scaled*;   { depth of previous box in the list }
    t: *small_number*;   { *type* of the node following a kern }
  begin *prev_p* ← p;   { an initial glue node is not a legal breakpoint }
  least_cost ← *awful_bad*; *do_all_six*(*set_height_zero*); *prev_dp* ← 0;
  loop begin ⟨ If node p is a legal breakpoint, check if this break is the best known, and **goto** *done* if p is
        null or if the page-so-far is already too full to accept more stuff 1026 ⟩;
    prev_p ← p; p ← *link*(*prev_p*);
    end;
done: *vert_break* ← *best_place*;
  end;

1025.   A global variable *best_height_plus_depth* will be set to the natural size of the box that corresponds
to the optimum breakpoint found by *vert_break*. (This value is used by the insertion-splitting algorithm of
the page builder.)

⟨ Global variables 13 ⟩ +≡
best_height_plus_depth: *scaled*;   { height of the best box, without stretching or shrinking }

1026. A subtle point to be noted here is that the maximum depth d might be negative, so *cur_height* and *prev_dp* might need to be corrected even after a glue or kern node.

⟨If node p is a legal breakpoint, check if this break is the best known, and **goto** *done* if p is null or if the page-so-far is already too full to accept more stuff 1026⟩ ≡

      end;
    if $(b = awful\_bad) \vee (pi \le eject\_penalty)$ **then goto** *done*;
    end

This code is used in section 1026.

1029.   ⟨ Compute the badness, b, using *awful_bad* if the box is too full 1029 ⟩ ≡
  if $cur\_height < h$ **then**
    if $(active\_height[3] \ne 0) \vee (active\_height[4] \ne 0) \vee (active\_height[5] \ne 0)$ **then** $b \leftarrow 0$
    else $b \leftarrow badness(h - cur\_height, active\_height[2])$
  else if $cur\_height - h > active\_height[6]$ **then** $b \leftarrow awful\_bad$
    else $b \leftarrow badness(cur\_height - h, active\_height[6])$

This code is used in section 1028.

1030.   Vertical lists that are subject to the *vert_break* procedure should not contain infinite shrinkability,
since that would permit any amount of information to "fit" on one page.

⟨ Update the current height and depth measurements with respect to a glue or kern node p 1030 ⟩ ≡
  if $type(p) = kern\_node$ **then** $q \leftarrow p$
  else begin $q \leftarrow glue\_ptr(p)$;
    $active\_height[2 + stretch\_order(q)] \leftarrow active\_height[2 + stretch\_order(q)] + stretch(q)$;
    $active\_height[6] \leftarrow active\_height[6] + shrink(q)$;
    if $(shrink\_order(q) \ne normal) \wedge (shrink(q) \ne 0)$ **then**
      begin
      $print\_err($"Infinite␣glue␣shrinkage␣found␣in␣box␣being␣split"$)$;
      $help4($"The␣box␣you␣are␣\vsplitting␣contains␣some␣infinitely"$)$
      $($"shrinkable␣glue,␣e.g.,␣`\vss´␣or␣`\vskip␣0pt␣minus␣1fil´."$)$
      $($"Such␣glue␣doesn´t␣belong␣there;␣but␣you␣can␣safely␣proceed,"$)$
      $($"since␣the␣offensive␣shrinkability␣has␣been␣made␣finite."$)$; $error$; $r \leftarrow new\_spec(q)$;
      $shrink\_order(r) \leftarrow normal$; $delete\_glue\_ref(q)$; $glue\_ptr(p) \leftarrow r$; $q \leftarrow r$;
      end;
    end;
  $cur\_height \leftarrow cur\_height + prev\_dp + width(q)$; $prev\_dp \leftarrow 0$

This code is used in section 1026.

1031.   Now we are ready to consider *vsplit* itself. Most of its work is accomplished by the two subroutines that we have just considered.

Given the number of a vlist box n, and given a desired page height h, the *vsplit* function finds the best initial segment of the vlist and returns a box for a page of height h. The remainder of the vlist, if any, replaces the original box, after removing glue and penalties and adjusting for *split_top_skip*. Mark nodes in the split-off box are used to set the values of *split_first_mark* and *split_bot_mark*; we use the fact that *split_first_mark* = *null* if and only if *split_bot_mark* = *null*.

The original box becomes "void" if and only if it has been entirely extracted. The extracted box is "void" if and only if the original box was void (or if it was, erroneously, an hlist box).

⟨ Declare the function called *do_marks* 1636 ⟩
function *vsplit*(*n* : *halfword*; *h* : *scaled*): *pointer*;   { extracts a page of height *h* from box *n* }
  label *exit*, *done*;
  var *v*: *pointer*;   { the box to be split }
    p: *pointer*;   { runs through the vlist }
    q: *pointer*;   { points to where the break occurs }
  begin *cur_val* ← *n*; *fetch_box*(*v*); *flush_node_list*(*split_disc*); *split_disc* ← *null*;
  if *sa_mark* ≠ *null* **then**
    if *do_marks*(*vsplit_init*, 0, *sa_mark*) **then** *sa_mark* ← *null*;
  if *split_first_mark* ≠ *null* **then**
    begin *delete_token_ref*(*split_first_mark*); *split_first_mark* ← *null*; *delete_token_ref*(*split_bot_mark*);
    split_bot_mark ← *null*;
    end;
  ⟨ Dispense with trivial cases of void or bad boxes 1032 ⟩;
  q ← *vert_break*(*list_ptr*(*v*), *h*, *split_max_depth*);
  ⟨ Look at all the marks in nodes before the break, and set the final link to *null* at the break 1033 ⟩;
  q ← *prune_page_top*(*q*, *saving_vdiscards* > 0); *p* ← *list_ptr*(*v*); *free_node*(*v*, *box_node_size*);
  if *q* ≠ *null* **then** *q* ← *vpack*(*q*, *natural*);
  change_box(*q*);   { the *eq_level* of the box stays the same }
  vsplit ← *vpackage*(*p*, *h*, *exactly*, *split_max_depth*);
exit: **end**;

1032.   ⟨ Dispense with trivial cases of void or bad boxes 1032 ⟩ ≡
  if *v* = *null* **then**
    begin *vsplit* ← *null*; **return**;
    end;
  if *type*(*v*) ≠ *vlist_node* **then**
    begin *print_err*(""); *print_esc*("vsplit"); *print*("␣needs␣a␣"); *print_esc*("vbox");
    help2("The␣box␣you␣are␣trying␣to␣split␣is␣an␣\hbox.")
    ("I␣can´t␣split␣such␣a␣box,␣so␣I´ll␣leave␣it␣alone."); *error*; *vsplit* ← *null*; **return**;
    end
This code is used in section 1031.

1033.   It's possible that the box begins with a penalty node that is the "best" break, so we must be careful to handle this special case correctly.

⟨ Look at all the marks in nodes before the break, and set the final link to *null* at the break 1033 ⟩ ≡
   $p \leftarrow list\_ptr(v)$;
   if $p = q$ **then** $list\_ptr(v) \leftarrow null$
   else loop begin if $type(p) = mark\_node$ **then**
         if $mark\_class(p) \neq 0$ **then** ⟨ Update the current marks for *vsplit* 1638 ⟩
         else if $split\_first\_mark = null$ **then**
               begin $split\_first\_mark \leftarrow mark\_ptr(p)$; $split\_bot\_mark \leftarrow split\_first\_mark$;
               $token\_ref\_count(split\_first\_mark) \leftarrow token\_ref\_count(split\_first\_mark) + 2$;
               end
            else begin $delete\_token\_ref(split\_bot\_mark)$; $split\_bot\_mark \leftarrow mark\_ptr(p)$;
               $add\_token\_ref(split\_bot\_mark)$;
               end;
      if $link(p) = q$ **then**
         begin $link(p) \leftarrow null$; **goto** *done*;
         end;
      $p \leftarrow link(p)$;
      end;
done:

This code is used in section 1031.

1034.   The page builder.   When TeX appends new material to its main vlist in vertical mode, it uses a method something like *vsplit* to decide where a page ends, except that the calculations are done "on line" as new items come in. The main complication in this process is that insertions must be put into their boxes and removed from the vlist, in a more-or-less optimum manner.

We shall use the term "current page" for that part of the main vlist that is being considered as a candidate for being broken off and sent to the user's output routine. The current page starts at *link*(*page_head*), and it ends at *page_tail*. We have *page_head* = *page_tail* if this list is empty.

Utter chaos would reign if the user kept changing page specifications while a page is being constructed, so the page builder keeps the pertinent specifications frozen as soon as the page receives its first box or insertion. The global variable *page_contents* is *empty* when the current page contains only mark nodes and content-less whatsit nodes; it is *inserts_only* if the page contains only insertion nodes in addition to marks and whatsits. Glue nodes, kern nodes, and penalty nodes are discarded until a box or rule node appears, at which time *page_contents* changes to *box_there*. As soon as *page_contents* becomes non-*empty*, the current *vsize* and *max_depth* are squirreled away into *page_goal* and *page_max_depth*; the latter values will be used until the page has been forwarded to the user's output routine. The \topskip adjustment is made when *page_contents* changes to *box_there*.

Although *page_goal* starts out equal to *vsize*, it is decreased by the scaled natural height-plus-depth of the insertions considered so far, and by the \skip corrections for those insertions. Therefore it represents the size into which the non-inserted material should fit, assuming that all insertions in the current page have been made.

The global variables *best_page_break* and *least_page_cost* correspond respectively to the local variables *best_place* and *least_cost* in the *vert_break* routine that we have already studied; i.e., they record the location and value of the best place currently known for breaking the current page. The value of *page_goal* at the time of the best break is stored in *best_size*.

> **define** *inserts_only* = 1   { *page_contents* when an insert node has been contributed, but no boxes }
> **define** *box_there* = 2   { *page_contents* when a box or rule has been contributed }

⟨ Global variables 13 ⟩ +≡
page_tail: *pointer*;   { the final node on the current page }
page_contents: *empty* .. *box_there*;   { what is on the current page so far? }
page_max_depth: *scaled*;   { maximum box depth on page being built }
best_page_break: *pointer*;   { break here to get the best page known so far }
least_page_cost: *integer*;   { the score for this currently best page }
best_size: *scaled*;   { its *page_goal* }

1035.   The page builder has another data structure to keep track of insertions. This is a list of four-word nodes, starting and ending at *page_ins_head*. That is, the first element of the list is node $r_1 = link(page\_ins\_head)$; node r_j is followed by $r_{j+1} = link(r_j)$; and if there are n items we have $r_{n+1} = page\_ins\_head$. The *subtype* field of each node in this list refers to an insertion number; for example, '\insert 250' would correspond to a node whose *subtype* is $qi(250)$ (the same as the *subtype* field of the relevant *ins_node*). These *subtype* fields are in increasing order, and $subtype(page\_ins\_head) = qi(255)$, so *page_ins_head* serves as a convenient sentinel at the end of the list. A record is present for each insertion number that appears in the current page.

The *type* field in these nodes distinguishes two possibilities that might occur as we look ahead before deciding on the optimum page break. If $type(r) = inserting$, then $height(r)$ contains the total of the height-plus-depth dimensions of the box and all its inserts seen so far. If $type(r) = split\_up$, then no more insertions will be made into this box, because at least one previous insertion was too big to fit on the current page; $broken\_ptr(r)$ points to the node where that insertion will be split, if TEX decides to split it, $broken\_ins(r)$ points to the insertion node that was tentatively split, and $height(r)$ includes also the natural height plus depth of the part that would be split off.

In both cases, $last\_ins\_ptr(r)$ points to the last *ins_node* encountered for box $qo(subtype(r))$ that would be at least partially inserted on the next page; and $best\_ins\_ptr(r)$ points to the last such *ins_node* that should actually be inserted, to get the page with minimum badness among all page breaks considered so far. We have $best\_ins\_ptr(r) = null$ if and only if no insertion for this box should be made to produce this optimum page.

The data structure definitions here use the fact that the *height* field appears in the fourth word of a box node.

define *page_ins_node_size* = 4   { number of words for a page insertion node }
define *inserting* = 0   { an insertion class that has not yet overflowed }
define *split_up* = 1   { an overflowed insertion class }
define $broken\_ptr(\#) \equiv link(\#+1)$ { an insertion for this class will break here if anywhere }
define $broken\_ins(\#) \equiv info(\#+1)$ { this insertion might break at *broken_ptr* }
define $last\_ins\_ptr(\#) \equiv link(\#+2)$ { the most recent insertion for this *subtype* }
define $best\_ins\_ptr(\#) \equiv info(\#+2)$ { the optimum most recent insertion }

⟨ Initialize the special list heads and constant nodes 838 ⟩ +≡
    $subtype(page\_ins\_head) \leftarrow qi(255)$; $type(page\_ins\_head) \leftarrow split\_up$; $link(page\_ins\_head) \leftarrow page\_ins\_head$;

1036. An array *page_so_far* records the heights and depths of everything on the current page. This array contains six *scaled* numbers, like the similar arrays already considered in *line_break* and *vert_break*; and it also contains *page_goal* and *page_depth*, since these values are all accessible to the user via *set_page_dimen* commands. The value of *page_so_far*[1] is also called *page_total*. The stretch and shrink components of the \skip corrections for each insertion are included in *page_so_far*, but the natural space components of these corrections are not, since they have been subtracted from *page_goal*.

The variable *page_depth* records the depth of the current page; it has been adjusted so that it is at most *page_max_depth*. The variable *last_glue* points to the glue specification of the most recent node contributed from the contribution list, if this was a glue node; otherwise *last_glue* = *max_halfword*. (If the contribution list is nonempty, however, the value of *last_glue* is not necessarily accurate.) The variables *last_penalty*, *last_kern*, and *last_node_type* are similar. And finally, *insert_penalties* holds the sum of the penalties associated with all split and floating insertions.

> **define** *page_goal* ≡ *page_so_far*[0]   { desired height of information on page being built }
> **define** *page_total* ≡ *page_so_far*[1]   { height of the current page }

        end;
      end;
    end
This code is used in section 244.

1041.   Here is a procedure that is called when the *page_contents* is changing from *empty* to *inserts_only*
or *box_there*.

  define *set_page_so_far_zero*(#) ≡ *page_so_far*[#] ← 0

procedure *freeze_page_specs*(*s* : *small_number*);
  begin *page_contents* ← *s*; *page_goal* ← *vsize*; *page_max_depth* ← *max_depth*; *page_depth* ← 0;
  do_all_six(*set_page_so_far_zero*); *least_page_cost* ← *awful_bad*;
  stat if *tracing_pages* > 0 **then**
    begin *begin_diagnostic*; *print_nl*("%%␣goal␣height="); *print_scaled*(*page_goal*);
    print(",␣max␣depth="); *print_scaled*(*page_max_depth*); *end_diagnostic*(*false*);
    end; **tats**
  end;

1042.   Pages are built by appending nodes to the current list in TEX's vertical mode, which is at the outermost level of the semantic nest. This vlist is split into two parts; the "current page" that we have been talking so much about already, and the "contribution list" that receives new nodes as they are created. The current page contains everything that the page builder has accounted for in its data structures, as described above, while the contribution list contains other things that have been generated by other parts of TEX but have not yet been seen by the page builder. The contribution list starts at *link*(*contrib_head*), and it ends at the current node in TEX's vertical mode.

When TEX has appended new material in vertical mode, it calls the procedure *build_page*, which tries to catch up by moving nodes from the contribution list to the current page. This procedure will succeed in its goal of emptying the contribution list, unless a page break is discovered, i.e., unless the current page has grown to the point where the optimum next page break has been determined. In the latter case, the nodes after the optimum break will go back onto the contribution list, and control will effectively pass to the user's output routine.

We make *type*(*page_head*) = *glue_node*, so that an initial glue node on the current page will not be considered a valid breakpoint.

⟨Initialize the special list heads and constant nodes 838⟩ +≡
    type(*page_head*) ← *glue_node*; *subtype*(*page_head*) ← *normal*;

1043.   The global variable *output_active* is true during the time the user's output routine is driving TEX.

⟨Global variables 13⟩ +≡
output_active: *boolean*;   { are we in the midst of an output routine? }

1044.   ⟨Set initial values of key variables 23⟩ +≡
    output_active ← *false*; *insert_penalties* ← 0;

1045.   The page builder is ready to start a fresh page if we initialize the following state variables. (However, the page insertion list is initialized elsewhere.)

⟨Start a new current page 1045⟩ ≡
    page_contents ← *empty*; *page_tail* ← *page_head*; *link*(*page_head*) ← *null*;
    last_glue ← *max_halfword*; *last_penalty* ← 0; *last_kern* ← 0; *last_node_type* ← −1; *page_depth* ← 0;
    page_max_depth ← 0
This code is used in sections 241 and 1071.

1046.   At certain times box 255 is supposed to be void (i.e., *null*), or an insertion box is supposed to be ready to accept a vertical list. If not, an error message is printed, and the following subroutine flushes the unwanted contents, reporting them to the user.

procedure *box_error*(*n* : *eight_bits*);
    begin *error*; *begin_diagnostic*; *print_nl*("The␣following␣box␣has␣been␣deleted:");
    show_box(*box*(*n*)); *end_diagnostic*(*true*); *flush_node_list*(*box*(*n*)); *box*(*n*) ← *null*;
    end;

1047. The following procedure guarantees that a given box register does not contain an \hbox.

procedure *ensure_vbox*(*n* : *eight_bits*);
  var *p*: *pointer*; { the box register contents }
  begin *p* ← *box*(*n*);
  if *p* ≠ *null* **then**
    if *type*(*p*) = *hlist_node* **then**
      begin *print_err*("Insertions␣can␣only␣be␣added␣to␣a␣vbox");
      help3("Tut␣tut:␣You´re␣trying␣to␣\insert␣into␣a")
      ("\box␣register␣that␣now␣contains␣an␣\hbox.")
      ("Proceed,␣and␣I´ll␣discard␣its␣present␣contents."); *box_error*(*n*);
      end;
  end;

1048. TEX is not always in vertical mode at the time *build_page* is called; the current mode reflects what TEX should return to, after the contribution list has been emptied. A call on *build_page* should be immediately followed by '**goto** *big_switch*', which is TEX's central control point.

  define *contribute* = 80 { go here to link a node into the current page }

⟨ Declare the procedure called *fire_up* 1066 ⟩
procedure *build_page*; { append contributions to the current page }
  label *exit*, *done*, *done1*, *continue*, *contribute*, *update_heights*;

  goto *contribute*;
  end

This code is used in section 1054.

1063.   We take note of the value of `\skip` n and the height plus depth of `\box` n only when the first `\insert` n node is encountered for a new page. A user who changes the contents of `\box` n after that first `\insert` n had better be either extremely careful or extremely lucky, or both.

⟨Create a page insertion node with $subtype(r) = qi(n)$, and include the glue correction for box n in the current page state 1063⟩ ≡
  begin $q \leftarrow get\_node(page\_ins\_node\_size)$; $link(q) \leftarrow link(r)$; $link(r) \leftarrow q$; $r \leftarrow q$; $subtype(r) \leftarrow qi(n)$;
  $type(r) \leftarrow inserting$; $ensure\_vbox(n)$;
  if $box(n) = null$ **then** $height(r) \leftarrow 0$
  else $height(r) \leftarrow height(box(n)) + depth(box(n))$;
  $best\_ins\_ptr(r) \leftarrow null$;
  $q \leftarrow skip(n)$;
  if $count(n) = 1000$ **then** $h \leftarrow height(r)$
  else $h \leftarrow x\_over\_n(height(r), 1000) * count(n)$;
  $page\_goal \leftarrow page\_goal - h - width(q)$;
  $page\_so\_far[2 + stretch\_order(q)] \leftarrow page\_so\_far[2 + stretch\_order(q)] + stretch(q)$;
  $page\_shrink \leftarrow page\_shrink + shrink(q)$;
  if $(shrink\_order(q) \neq normal) \wedge (shrink(q) \neq 0)$ **then**
    begin $print\_err(\texttt{"Infinite␣glue␣shrinkage␣inserted␣from␣"})$; $print\_esc(\texttt{"skip"})$; $print\_int(n)$;
    $help3(\texttt{"The␣correction␣glue␣for␣page␣breaking␣with␣insertions"})$
    $(\texttt{"must␣have␣finite␣shrinkability.␣But␣you␣may␣proceed,"})$
    $(\texttt{"since␣the␣offensive␣shrinkability␣has␣been␣made␣finite."})$; $error$;
    end;
  end

This code is used in section 1062.

1064.   Here is the code that will split a long footnote between pages, in an emergency. The current situation deserves to be recapitulated: Node p is an insertion into box n; the insertion will not fit, in its entirety, either because it would make the total contents of box n greater than `\dimen` n, or because it would make the incremental amount of growth h greater than the available space $delta$, or both. (This amount h has been weighted by the insertion scaling factor, i.e., by `\count` n over 1000.) Now we will choose the best way to break the vlist of the insertion, using the same criteria as in the `\vsplit` operation.

⟨Find the best way to split the insertion, and change $type(r)$ to $split\_up$ 1064⟩ ≡
  begin if $count(n) \leq 0$ **then** $w \leftarrow max\_dimen$
  else begin $w \leftarrow page\_goal - page\_total - page\_depth$;
    if $count(n) \neq 1000$ **then** $w \leftarrow x\_over\_n(w, count(n)) * 1000$;
    end;
  if $w > dimen(n) - height(r)$ **then** $w \leftarrow dimen(n) - height(r)$;
  $q \leftarrow vert\_break(ins\_ptr(p), w, depth(p))$; $height(r) \leftarrow height(r) + best\_height\_plus\_depth$;
  stat if $tracing\_pages > 0$ **then** ⟨Display the insertion split cost 1065⟩;
  tats
  if $count(n) \neq 1000$ **then** $best\_height\_plus\_depth \leftarrow x\_over\_n(best\_height\_plus\_depth, 1000) * count(n)$;
  $page\_goal \leftarrow page\_goal - best\_height\_plus\_depth$; $type(r) \leftarrow split\_up$; $broken\_ptr(r) \leftarrow q$;
  $broken\_ins(r) \leftarrow p$;
  if $q = null$ **then** $insert\_penalties \leftarrow insert\_penalties + eject\_penalty$
  else if $type(q) = penalty\_node$ **then** $insert\_penalties \leftarrow insert\_penalties + penalty(q)$;
  end

This code is used in section 1062.

1065. ⟨Display the insertion split cost 1065⟩ ≡
  begin *begin_diagnostic*; *print_nl*("%␣split"); *print_int*(*n*); *print*("␣to␣"); *print_scaled*(*w*);
  print_char(","); *print_scaled*(*best_height_plus_depth*);
  print("␣p=");
  if *q* = *null* **then** *print_int*(*eject_penalty*)
  else if *type*(*q*) = *penalty_node* **then** *print_int*(*penalty*(*q*))
    else *print_char*("0");
  end_diagnostic(*false*);
  end

This code is used in section 1064.

1066. When the page builder has looked at as much material as could appear before the next page break,
it makes its decision. The break that gave minimum badness will be used to put a completed "page" into
box 255, with insertions appended to their other boxes.

We also set the values of *top_mark*, *first_mark*, and *bot_mark*. The program uses the fact that *bot_mark* ≠
null implies *first_mark* ≠ *null*; it also knows that *bot_mark* = *null* implies *top_mark* = *first_mark* = *null*.

The *fire_up* subroutine prepares to output the current page at the best place; then it fires up the user's
output routine, if there is one, or it simply ships out the page. There is one parameter, *c*, which represents
the node that was being contributed to the page when the decision to force an output was made.

⟨Declare the procedure called *fire_up* 1066⟩ ≡
procedure *fire_up*(*c* : *pointer*);
  label *exit*;
  var *p, q, r, s*: *pointer*;   {nodes being examined and/or changed}
    prev_p: *pointer*;   {predecessor of *p*}
    n: *min_quarterword* .. *biggest_reg*;   {insertion box number}
    wait: *boolean*;   {should the present insertion be held over?}
    save_vbadness: *integer*;   {saved value of *vbadness*}
    save_vfuzz: *scaled*;   {saved value of *vfuzz*}
    save_split_top_skip: *pointer*;   {saved value of *split_top_skip*}
  begin ⟨Set the value of *output_penalty* 1067⟩;
  if *sa_mark* ≠ *null* **then**
    if *do_marks*(*fire_up_init*, 0, *sa_mark*) **then** *sa_mark* ← *null*;
  if *bot_mark* ≠ *null* **then**
    begin if *top_mark* ≠ *null* **then** *delete_token_ref*(*top_mark*);
    top_mark ← *bot_mark*; *add_token_ref*(*top_mark*); *delete_token_ref*(*first_mark*); *first_mark* ← *null*;
    end;
  ⟨Put the optimal current page into box 255, update *first_mark* and *bot_mark*, append insertions to their
      boxes, and put the remaining nodes back on the contribution list 1068⟩;
  if *sa_mark* ≠ *null* **then**
    if *do_marks*(*fire_up_done*, 0, *sa_mark*) **then** *sa_mark* ← *null*;
  if (*top_mark* ≠ *null*) ∧ (*first_mark* = *null*) **then**
    begin *first_mark* ← *top_mark*; *add_token_ref*(*top_mark*);
    end;
  if *output_routine* ≠ *null* **then**
    if *dead_cycles* ≥ *max_dead_cycles* **then**
      ⟨Explain that too many dead cycles have occurred in a row 1078⟩
    else ⟨Fire up the user's output routine and **return** 1079⟩;
  ⟨Perform the default output routine 1077⟩;
exit: **end**;

This code is used in section 1048.

1067. ⟨Set the value of *output_penalty* 1067⟩ ≡
  if *type*(*best_page_break*) = *penalty_node* **then**
    begin *geq_word_define*(*int_base* + *output_penalty_code*, *penalty*(*best_page_break*));
    penalty(*best_page_break*) ← *inf_penalty*;
    end
  else *geq_word_define*(*int_base* + *output_penalty_code*, *inf_penalty*)

This code is used in section 1066.

1068. As the page is finally being prepared for output, pointer *p* runs through the vlist, with *prev_p* trailing behind; pointer *q* is the tail of a list of insertions that are being held over for a subsequent page.

⟨Put the optimal current page into box 255, update *first_mark* and *bot_mark*, append insertions to their
    boxes, and put the remaining nodes back on the contribution list 1068⟩ ≡
  if *c* = *best_page_break* **then** *best_page_break* ← *null*;   {*c* not yet linked in}
  ⟨Ensure that box 255 is empty before output 1069⟩;
  insert_penalties ← 0;   {this will count the number of insertions held over}
  save_split_top_skip ← *split_top_skip*;
  if *holding_inserts* ≤ 0 **then** ⟨Prepare all the boxes involved in insertions to act as queues 1072⟩;
  q ← *hold_head*; *link*(*q*) ← *null*; *prev_p* ← *page_head*; *p* ← *link*(*prev_p*);
  while *p* ≠ *best_page_break* **do**
    begin if *type*(*p*) = *ins_node* **then**
      begin if *holding_inserts* ≤ 0 **then** ⟨Either insert the material specified by node *p* into the
          appropriate box, or hold it for the next page; also delete node *p* from the current page 1074⟩;
      end
    else if *type*(*p*) = *mark_node* **then**
        if *mark_class*(*p*) ≠ 0 **then** ⟨Update the current marks for *fire_up* 1641⟩
        else ⟨Update the values of *first_mark* and *bot_mark* 1070⟩;
    prev_p ← *p*; *p* ← *link*(*prev_p*);
    end;
  split_top_skip ← *save_split_top_skip*; ⟨Break the current page at node *p*, put it in box 255, and put the
    remaining nodes on the contribution list 1071⟩;
  ⟨Delete the page-insertion nodes 1073⟩

This code is used in section 1066.

1069. ⟨Ensure that box 255 is empty before output 1069⟩ ≡
  if *box*(255) ≠ *null* **then**
    begin *print_err*(""); *print_esc*("box"); *print*("255␣is␣not␣void");
    help2("You␣shouldn´t␣use␣\box255␣except␣in␣\output␣routines.")
    ("Proceed,␣and␣I´ll␣discard␣its␣present␣contents."); *box_error*(255);
    end

This code is used in section 1068.

1070. ⟨Update the values of *first_mark* and *bot_mark* 1070⟩ ≡
  begin if *first_mark* = *null* **then**
    begin *first_mark* ← *mark_ptr*(*p*); *add_token_ref*(*first_mark*);
    end;
  if *bot_mark* ≠ *null* **then** *delete_token_ref*(*bot_mark*);
  bot_mark ← *mark_ptr*(*p*); *add_token_ref*(*bot_mark*);
  end

This code is used in section 1068.

1071. When the following code is executed, the current page runs from node *link*(*page_head*) to node *prev_p*, and the nodes from *p* to *page_tail* are to be placed back at the front of the contribution list. Furthermore the heldover insertions appear in a list from *link*(*hold_head*) to *q*; we will put them into the current page list for safekeeping while the user's output routine is active. We might have *q* = *hold_head*; and *p* = *null* if and only if *prev_p* = *page_tail*. Error messages are suppressed within *vpackage*, since the box might appear to be overfull or underfull simply because the stretch and shrink from the \skip registers for inserts are not actually present in the box.

⟨ Break the current page at node *p*, put it in box 255, and put the remaining nodes on the contribution
      list 1071 ⟩ ≡
  if *p* ≠ *null* **then**
    begin if *link*(*contrib_head*) = *null* **then**
      if *nest_ptr* = 0 **then** *tail* ← *page_tail*
      else *contrib_tail* ← *page_tail*;
    link(*page_tail*) ← *link*(*contrib_head*); *link*(*contrib_head*) ← *p*; *link*(*prev_p*) ← *null*;
    end;
  save_vbadness ← *vbadness*; *vbadness* ← *inf_bad*; *save_vfuzz* ← *vfuzz*; *vfuzz* ← *max_dimen*;
      { inhibit error messages }
  box(255) ← *vpackage*(*link*(*page_head*), *best_size*, *exactly*, *page_max_depth*); *vbadness* ← *save_vbadness*;
  vfuzz ← *save_vfuzz*;
  if *last_glue* ≠ *max_halfword* **then** *delete_glue_ref*(*last_glue*);
  ⟨ Start a new current page 1045 ⟩;   { this sets *last_glue* ← *max_halfword* }
  if *q* ≠ *hold_head* **then**
    begin *link*(*page_head*) ← *link*(*hold_head*); *page_tail* ← *q*;
    end

This code is used in section 1068.

1072. If many insertions are supposed to go into the same box, we want to know the position of the last node in that box, so that we don't need to waste time when linking further information into it. The *last_ins_ptr* fields of the page insertion nodes are therefore used for this purpose during the packaging phase.

⟨ Prepare all the boxes involved in insertions to act as queues 1072 ⟩ ≡
  begin *r* ← *link*(*page_ins_head*);
  while *r* ≠ *page_ins_head* **do**
    begin if *best_ins_ptr*(*r*) ≠ *null* **then**
      begin *n* ← *qo*(*subtype*(*r*)); *ensure_vbox*(*n*);
      if *box*(*n*) = *null* **then** *box*(*n*) ← *new_null_box*;
      p ← *box*(*n*) + *list_offset*;
      while *link*(*p*) ≠ *null* **do** *p* ← *link*(*p*);
      last_ins_ptr(*r*) ← *p*;
      end;
    r ← *link*(*r*);
    end;
  end

This code is used in section 1068.

1073. ⟨ Delete the page-insertion nodes 1073 ⟩ ≡
  r ← *link*(*page_ins_head*);
  while *r* ≠ *page_ins_head* **do**
    begin *q* ← *link*(*r*); *free_node*(*r*, *page_ins_node_size*); *r* ← *q*;
    end;
  link(*page_ins_head*) ← *page_ins_head*

This code is used in section 1068.

1074. We will set *best_ins_ptr* ← *null* and package the box corresponding to insertion node *r*, just after making the final insertion into that box. If this final insertion is '*split_up*', the remainder after splitting and pruning (if any) will be carried over to the next page.

⟨ Either insert the material specified by node *p* into the appropriate box, or hold it for the next page; also
        delete node *p* from the current page 1074 ⟩ ≡
  begin *r* ← *link*(*page_ins_head*);
  while *subtype*(*r*) ≠ *subtype*(*p*) **do** *r* ← *link*(*r*);
  if *best_ins_ptr*(*r*) = *null* **then** *wait* ← *true*
  else begin *wait* ← *false*; *s* ← *last_ins_ptr*(*r*); *link*(*s*) ← *ins_ptr*(*p*);
    if *best_ins_ptr*(*r*) = *p* **then** ⟨ Wrap up the box specified by node *r*, splitting node *p* if called for; set
            wait ← *true* if node *p* holds a remainder after splitting 1075 ⟩
    else begin while *link*(*s*) ≠ *null* **do** *s* ← *link*(*s*);
      last_ins_ptr(*r*) ← *s*;
      end;
    end;
  ⟨ Either append the insertion node *p* after node *q*, and remove it from the current page, or delete
        node(*p*) 1076 ⟩;
  end

This code is used in section 1068.

1075. ⟨ Wrap up the box specified by node *r*, splitting node *p* if called for; set *wait* ← *true* if node *p*
        holds a remainder after splitting 1075 ⟩ ≡
  begin if *type*(*r*) = *split_up* **then**
    if (*broken_ins*(*r*) = *p*) ∧ (*broken_ptr*(*r*) ≠ *null*) **then**
      begin while *link*(*s*) ≠ *broken_ptr*(*r*) **do** *s* ← *link*(*s*);
      link(*s*) ← *null*; *split_top_skip* ← *split_top_ptr*(*p*); *ins_ptr*(*p*) ← *prune_page_top*(*broken_ptr*(*r*), *false*);
      if *ins_ptr*(*p*) ≠ *null* **then**
        begin *temp_ptr* ← *vpack*(*ins_ptr*(*p*), *natural*); *height*(*p*) ← *height*(*temp_ptr*) + *depth*(*temp_ptr*);
        free_node(*temp_ptr*, *box_node_size*); *wait* ← *true*;
        end;
      end;
  best_ins_ptr(*r*) ← *null*; *n* ← *qo*(*subtype*(*r*)); *temp_ptr* ← *list_ptr*(*box*(*n*));
  free_node(*box*(*n*), *box_node_size*); *box*(*n*) ← *vpack*(*temp_ptr*, *natural*);
  end

This code is used in section 1074.

1076. ⟨ Either append the insertion node *p* after node *q*, and remove it from the current page, or delete
        node(*p*) 1076 ⟩ ≡
  link(*prev_p*) ← *link*(*p*); *link*(*p*) ← *null*;
  if *wait* **then**
    begin *link*(*q*) ← *p*; *q* ← *p*; *incr*(*insert_penalties*);
    end
  else begin *delete_glue_ref*(*split_top_ptr*(*p*)); *free_node*(*p*, *ins_node_size*);
    end;
  p ← *prev_p*

This code is used in section 1074.

1077. The list of heldover insertions, running from $link(page\_head)$ to $page\_tail$, must be moved to the contribution list when the user has specified no output routine.

⟨ Perform the default output routine 1077 ⟩ ≡
  begin if $link(page\_head) \neq null$ **then**
    begin if $link(contrib\_head) = null$ **then**
      if $nest\_ptr = 0$ **then** $tail \leftarrow page\_tail$ **else** $contrib\_tail \leftarrow page\_tail$
    else $link(page\_tail) \leftarrow link(contrib\_head)$;
    $link(contrib\_head) \leftarrow link(page\_head)$; $link(page\_head) \leftarrow null$; $page\_tail \leftarrow page\_head$;
    end;
  $flush\_node\_list(page\_disc)$; $page\_disc \leftarrow null$; $ship\_out(box(255))$; $box(255) \leftarrow null$;
  end

This code is used in section 1066.

1078. ⟨ Explain that too many dead cycles have occurred in a row 1078 ⟩ ≡
  begin $print\_err("Output_{\sqcup}loop---")$; $print\_int(dead\_cycles)$; $print("_{\sqcup}consecutive_{\sqcup}dead_{\sqcup}cycles")$;
  $help3("I´ve_{\sqcup}concluded_{\sqcup}that_{\sqcup}your_{\sqcup}\backslash output_{\sqcup}is_{\sqcup}awry;_{\sqcup}it_{\sqcup}never_{\sqcup}does_{\sqcup}a")$
  $("\backslash shipout,_{\sqcup}so_{\sqcup}I´m_{\sqcup}shipping_{\sqcup}\backslash box255_{\sqcup}out_{\sqcup}myself._{\sqcup}Next_{\sqcup}time")$
  $("increase_{\sqcup}\backslash maxdeadcycles_{\sqcup}if_{\sqcup}you_{\sqcup}want_{\sqcup}me_{\sqcup}to_{\sqcup}be_{\sqcup}more_{\sqcup}patient!")$; $error$;
  end

This code is used in section 1066.

1079. ⟨ Fire up the user's output routine and **return** 1079 ⟩ ≡
  begin $output\_active \leftarrow true$; $incr(dead\_cycles)$; $push\_nest$; $mode \leftarrow -vmode$;
  $prev\_depth \leftarrow ignore\_depth$; $mode\_line \leftarrow -line$; $begin\_token\_list(output\_routine, output\_text)$;
  $new\_save\_level(output\_group)$; $normal\_paragraph$; $scan\_left\_brace$; **return**;
  end

This code is used in section 1066.

1080. When the user's output routine finishes, it has constructed a vlist in internal vertical mode, and TEX will do the following:

⟨ Resume the page builder after an output routine has come to an end 1080 ⟩ ≡
  begin if $(loc \neq null) \vee ((token\_type \neq output\_text) \wedge (token\_type \neq backed\_up))$ **then**
    ⟨ Recover from an unbalanced output routine 1081 ⟩;
  end_token_list;   { conserve stack space in case more outputs are triggered }
  end_graf; $unsave$; $output\_active \leftarrow false$; $insert\_penalties \leftarrow 0$;
  ⟨ Ensure that box 255 is empty after output 1082 ⟩;
  if $tail \neq head$ **then**   { current list goes after heldover insertions }
    begin $link(page\_tail) \leftarrow link(head)$; $page\_tail \leftarrow tail$;
    end;
  if $link(page\_head) \neq null$ **then**   { and both go before heldover contributions }
    begin if $link(contrib\_head) = null$ **then** $contrib\_tail \leftarrow page\_tail$;
    $link(page\_tail) \leftarrow link(contrib\_head)$; $link(contrib\_head) \leftarrow link(page\_head)$; $link(page\_head) \leftarrow null$;
    $page\_tail \leftarrow page\_head$;
    end;
  $flush\_node\_list(page\_disc)$; $page\_disc \leftarrow null$; pop_nest; $build\_page$;
  end

This code is used in section 1154.

1081. ⟨Recover from an unbalanced output routine 1081⟩ ≡
  begin *print_err*("Unbalanced␣output␣routine");
  help2("Your␣sneaky␣output␣routine␣has␣problematic␣{´s␣and/or␣}´s.")
  ("I␣can´t␣handle␣that␣very␣well;␣good␣luck."); *error*;
  repeat *get_token*;
  until *loc* = *null*;
  end   { loops forever if reading from a file, since *null* = *min_halfword* ≤ 0 }
This code is used in section 1080.

1082. ⟨Ensure that box 255 is empty after output 1082⟩ ≡
  if *box*(255) ≠ *null* **then**
    begin *print_err*("Output␣routine␣didn´t␣use␣all␣of␣"); *print_esc*("box"); *print_int*(255);
    help3("Your␣\output␣commands␣should␣empty␣\box255,")
    ("e.g.,␣by␣saying␣`\shipout\box255´.")
    ("Proceed;␣I´ll␣discard␣its␣present␣contents."); *box_error*(255);
    end
This code is used in section 1080.

468 PART 46: THE CHIEF EXECUTIVE

1083.   The chief executive.   We come now to the *main_control* routine, which contains the master switch that causes all the various pieces of TEX to do their things, in the right order.

In a sense, this is the grand climax of the program: It applies all the tools that we have worked so hard to construct. In another sense, this is the messiest part of the program: It necessarily refers to other pieces of code all over the place, so that a person can't fully understand what is going on without paging back and forth to be reminded of conventions that are defined elsewhere. We are now at the hub of the web, the central nervous system that touches most of the other parts and ties them together.

The structure of *main_control* itself is quite simple. There's a label called *big_switch*, at which point the next token of input is fetched using *get_x_token*. Then the program branches at high speed into one of about 100 possible directions, based on the value of the current mode and the newly fetched command code; the sum $abs(mode) + cur\_cmd$ indicates what to do next. For example, the case '*vmode + letter*' arises when a letter occurs in vertical mode (or internal vertical mode); this case leads to instructions that initialize a new paragraph and enter horizontal mode.

The big **case** statement that contains this multiway switch has been labeled *reswitch*, so that the program can **goto** *reswitch* when the next token has already been fetched. Most of the cases are quite short; they call an "action procedure" that does the work for that case, and then they either **goto** *reswitch* or they "fall through" to the end of the **case** statement, which returns control back to *big_switch*. Thus, *main_control* is not an extremely large procedure, in spite of the multiplicity of things it must do; it is small enough to be handled by Pascal compilers that put severe restrictions on procedure size.

One case is singled out for special treatment, because it accounts for most of TEX's activities in typical applications. The process of reading simple text and converting it into *char_node* records, while looking for ligatures and kerns, is part of TEX's "inner loop"; the whole program runs efficiently when its inner loop is fast, so this part has been written with particular care.

1084.   We shall concentrate first on the inner loop of *main_control*, deferring consideration of the other cases until later.

 define *big_switch* = 60 { go here to branch on the next token of input }
 define *main_loop* = 70 { go here to typeset a string of consecutive characters }
 define *collect_native* = 71 { go here to collect characters in a "native" font string }
 define *collected* = 72
 define *main_loop_wrapup* = 80 { go here to finish a character or ligature }
 define *main_loop_move* = 90 { go here to advance the ligature cursor }
 define *main_loop_move_lig* = 95 { same, when advancing past a generated ligature }
 define *main_loop_lookahead* = 100 { go here to bring in another character, if any }
 define *main_lig_loop* = 110 { go here to check for ligatures or kerning }
 define *append_normal_space* = 120 { go here to append a normal space between words }

 define *pdfbox_crop* = 1 { *pdf_box_type* passed to *find_pic_file* }
 define *pdfbox_media* = 2
 define *pdfbox_bleed* = 3
 define *pdfbox_trim* = 4
 define *pdfbox_art* = 5
 define *pdfbox_none* = 6

⟨ Declare action procedures for use by *main_control* 1097 ⟩
⟨ Declare the procedure called *handle_right_brace* 1122 ⟩
procedure *main_control*; { governs TEX's activities }

This code is used in section 1084.

1086.   The following part of the program was first written in a structured manner, according to the philosophy that "premature optimization is the root of all evil." Then it was rearranged into pieces of spaghetti so that the most common actions could proceed with little or no redundancy.

  The original unoptimized form of this algorithm resembles the *reconstitute* procedure, which was described earlier in connection with hyphenation. Again we have an implied "cursor" between characters *cur_l* and *cur_r*. The main difference is that the *lig_stack* can now contain a charnode as well as pseudo-ligatures; that stack is now usually nonempty, because the next character of input (if any) has been appended to it. In *main_control* we have

$$cur\_r = \begin{cases} character(lig\_stack), & \text{if } lig\_stack > null; \\ font\_bchar[cur\_font], & \text{otherwise;} \end{cases}$$

except when *character*(*lig_stack*) = *font_false_bchar*[*cur_font*]. Several additional global variables are needed.

⟨ Global variables 13 ⟩ +≡
main_f: *internal_font_number*;   { the current font }
main_i: *four_quarters*;   { character information bytes for *cur_l* }
main_j: *four_quarters*;   { ligature/kern command }
main_k: *font_index*;   { index into *font_info* }
main_p: *pointer*;   { temporary register for list manipulation }
main_pp, *main_ppp*: *pointer*;   { more temporary registers for list manipulation }
main_h: *pointer*;   { temp for hyphen offset in native-font text }
is_hyph: *boolean*;   { whether the last char seen is the font's hyphenchar }
space_class: *integer*;
prev_class: *integer*;
main_s: *integer*;   { space factor value }
bchar: *halfword*;   { boundary character of current font, or *non_char* }
false_bchar: *halfword*;   { nonexistent character matching *bchar*, or *non_char* }
cancel_boundary: *boolean*;   { should the left boundary be ignored? }
ins_disc: *boolean*;   { should we insert a discretionary node? }

1087.   The boolean variables of the main loop are normally false, and always reset to false before the loop is left. That saves us the extra work of initializing each time.

⟨ Set initial values of key variables 23 ⟩ +≡
  ligature_present ← *false*; *cancel_boundary* ← *false*; *lft_hit* ← *false*; *rt_hit* ← *false*; *ins_disc* ← *false*;

1088.   We leave the *space_factor* unchanged if *sf_code*(*cur_chr*) = 0; otherwise we set it equal to *sf_code*(*cur_chr*), except that it should never change from a value less than 1000 to a value exceeding 1000. The most common case is *sf_code*(*cur_chr*) = 1000, so we want that case to be fast.

The overall structure of the main loop is presented here. Some program labels are inside the individual sections.

  if *cur_r* = *false_bchar* then *cur_r* ← *non_char*   { this prevents spurious ligatures }

This code is used in section 1088.

1093.   Even though comparatively few characters have a lig/kern program, several of the instructions here count as part of TEX's inner loop, since a potentially long sequential search must be performed. For example, tests with Computer Modern Roman showed that about 40 per cent of all characters actually encountered in practice had a lig/kern program, and that about four lig/kern commands were investigated for every such character.

At the beginning of this code we have $main\_i = char\_info(main\_f)(cur\_l)$.

⟨If there's a ligature/kern command relevant to cur_l and cur_r, adjust the text appropriately; exit to $main\_loop\_wrapup$ 1093⟩ ≡

  if $char\_tag(main\_i) \neq lig\_tag$ **then goto** $main\_loop\_wrapup$;

  if $cur\_r = non\_char$ **then goto** $main\_loop\_wrapup$;

  if *cur_l* < *non_char* **then goto** *main_lig_loop*;
  main_k ← *bchar_label*[*main_f*]; **goto** *main_lig_loop* + 1;
  end

This code is used in section 1093.

1095.   The occurrence of blank spaces is almost part of TEX's inner loop, since we usually encounter about one space for every five non-blank characters. Therefore *main_control* gives second-highest priority to ordinary spaces.

When a glue parameter like \spaceskip is set to '0pt', we will see to it later that the corresponding glue specification is precisely *zero_glue*, not merely a pointer to some specification that happens to be full of zeroes. Therefore it is simple to test whether a glue parameter is zero or not.

⟨Append a normal inter-word space to the current list, then **goto** *big_switch* 1095⟩ ≡
  if *space_skip* = *zero_glue* **then**
    begin ⟨Find the glue specification, *main_p*, for text spaces in the current font 1096⟩;
    temp_ptr ← *new_glue*(*main_p*);
    end
  else *temp_ptr* ← *new_param_glue*(*space_skip_code*);
  link(*tail*) ← *temp_ptr*; *tail* ← *temp_ptr*; **goto** *big_switch*
This code is used in section 1084.

1096.   Having *font_glue* allocated for each text font saves both time and memory. If any of the three spacing parameters are subsequently changed by the use of \fontdimen, the *find_font_dimen* procedure deallocates the *font_glue* specification allocated here.

⟨Find the glue specification, *main_p*, for text spaces in the current font 1096⟩ ≡
  begin *main_p* ← *font_glue*[*cur_font*];
  if *main_p* = *null* **then**
    begin *main_p* ← *new_spec*(*zero_glue*); *main_k* ← *param_base*[*cur_font*] + *space_code*;
    width(*main_p*) ← *font_info*[*main_k*].*sc*;   { that's *space*(*cur_font*) }

⟨ Cases of *main_control* that are for extensions to TEX 1402 ⟩

This code is used in section 1084.

1100. Here is a list of cases where the user has probably gotten into or out of math mode by mistake. TEX will insert a dollar sign and rescan the current token.

define $non\_math(\#) \equiv vmode + \#, hmode + \#$

⟨ Math-only cases in non-math modes, or vice versa 1100 ⟩ ≡
  $non\_math(sup\_mark), non\_math(sub\_mark), non\_math(math\_char\_num), non\_math(math\_given)$,
    $non\_math(XeTeX\_math\_given), non\_math(math\_comp), non\_math(delim\_num), non\_math(left\_right)$,
    $non\_math(above), non\_math(radical), non\_math(math\_style), non\_math(math\_choice)$,
    $non\_math(vcenter), non\_math(non\_script), non\_math(mkern), non\_math(limit\_switch)$,
    $non\_math(mskip), non\_math(math\_accent), mmode + endv, mmode + par\_end, mmode + stop$,
    $mmode + vskip, mmode + un\_vbox, mmode + valign, mmode + hrule$
This code is used in section 1099.

1101. ⟨ Declare action procedures for use by *main_control* 1097 ⟩ +≡
procedure *insert_dollar_sign*;
  begin *back_input*; $cur_tok \leftarrow math_shift_token + $ "$"; *print_err*("Missing␣$␣inserted");
  help2("I´ve␣inserted␣a␣begin-math/end-math␣symbol␣since␣I␣think")
  ("you␣left␣one␣out.␣Proceed,␣with␣fingers␣crossed."); *ins_error*;
  end;

1102. When erroneous situations arise, TEX usually issues an error message specific to the particular error. For example, '\noalign' should not appear in any mode, since it is recognized by the *align_peek* routine in all of its legitimate appearances; a special error message is given when '\noalign' occurs elsewhere. But sometimes the most appropriate error message is simply that the user is not allowed to do what he or she has attempted. For example, '\moveleft' is allowed only in vertical mode, and '\lower' only in non-vertical modes. Such cases are enumerated here and in the other sections referred to under 'See also . . . .'

⟨Forbidden cases detected in *main_control* 1102⟩ ≡
  vmode + *vmove*, *hmode* + *hmove*, *mmode* + *hmove*, *any_mode*(*last_item*),

See also sections 1152, 1165, and 1198.

This code is used in section 1099.

1103. The '*you_cant*' procedure prints a line saying that the current command is illegal in the current mode; it identifies these things symbolically.

⟨Declare action procedures for use by *main_control* 1097⟩ +≡
procedure *you_cant*;
  begin *print_err*("You␣can´t␣use␣`"); *print_cmd_chr*(*cur_cmd*, *cur_chr*); *print*("´␣in␣");
  print_mode(*mode*);
  end;

1104. ⟨Declare action procedures for use by *main_control* 1097⟩ +≡
procedure *report_illegal_case*;
  begin *you_cant*; *help4*("Sorry,␣but␣I´m␣not␣programmed␣to␣handle␣this␣case;")
  ("I´ll␣just␣pretend␣that␣you␣didn´t␣ask␣for␣it.")
  ("If␣you´re␣in␣the␣wrong␣mode,␣you␣might␣be␣able␣to")
  ("return␣to␣the␣right␣one␣by␣typing␣`I}´␣or␣`I$´␣or␣`I\par´.");
  error;
  end;

1105. Some operations are allowed only in privileged modes, i.e., in cases that *mode* > 0. The *privileged* function is used to detect violations of this rule; it issues an error message and returns *false* if the current *mode* is negative.

⟨Declare action procedures for use by *main_control* 1097⟩ +≡
function *privileged*: *boolean*;
  begin if *mode* > 0 **then** *privileged* ← *true*
  else begin *report_illegal_case*; *privileged* ← *false*;
    end;
  end;

1106. Either \dump or \end will cause *main_control* to enter the endgame, since both of them have '*stop*' as their command code.

⟨Put each of TEX's primitives into the hash table 252⟩ +≡
  primitive("end", *stop*, 0);
  primitive("dump", *stop*, 1);

1107. ⟨Cases of *print_cmd_chr* for symbolic printing of primitives 253⟩ +≡
stop: **if** *chr_code* = 1 **then** *print_esc*("dump") **else** *print_esc*("end");

1108.   We don't want to leave *main_control* immediately when a *stop* command is sensed, because it may be necessary to invoke an \output routine several times before things really grind to a halt. (The output routine might even say '\gdef\end{...}', to prolong the life of the job.) Therefore *its_all_over* is *true* only when the current page and contribution list are empty, and when the last output was not a "dead cycle."

⟨ Declare action procedures for use by *main_control* 1097 ⟩ +≡

function *its_all_over* : *boolean*;   { do this when \end or \dump occurs }
 label *exit*;
 begin if *privileged* **then**
  begin if (*page_head* = *page_tail*) ∧ (*head* = *tail*) ∧ (*dead_cycles* = 0) **then**
   begin *its_all_over* ← *true*; **return**;
   end;
  back_input;   { we will try to end again after ejecting residual material }
  tail_append(*new_null_box*); *width*(*tail*) ← *hsize*; *tail_append*(*new_glue*(*fill_glue*));
  tail_append(*new_penalty*(−´10000000000));
  build_page;   { append \hbox to \hsize{}\vfill\penalty-'10000000000 }
  end;
 its_all_over ← *false*;
exit: **end**;

1109.   Building boxes and lists.   The most important parts of *main_control* are concerned with TEX's chief mission of box-making. We need to control the activities that put entries on vlists and hlists, as well as the activities that convert those lists into boxes. All of the necessary machinery has already been developed; it remains for us to "push the buttons" at the right times.

1110.   As an introduction to these routines, let's consider one of the simplest cases: What happens when '\hrule' occurs in vertical mode, or '\vrule' in horizontal mode or math mode? The code in *main_control* is short, since the *scan_rule_spec* routine already does most of what is required; thus, there is no need for a special action procedure.

Note that baselineskip calculations are disabled after a rule in vertical mode, by setting *prev_depth* ← *ignore_depth*.

⟨ Cases of *main_control* that build boxes and lists 1110 ⟩ ≡
vmode + *hrule*, *hmode* + *vrule*, *mmode* + *vrule*: **begin** *tail_append*(*scan_rule_spec*);
    if *abs*(*mode*) = *vmode* **then** *prev_depth* ← *ignore_depth*
    else if *abs*(*mode*) = *hmode* **then** *space_factor* ← 1000;
    end;

See also sections 1111, 1117, 1121, 1127, 1144, 1146, 1148, 1151, 1156, 1158, 1163, 1166, 1170, 1176, 1180, 1184, 1188, 1191, 1194, 1204, 1208, 1212, 1216, 1218, 1221, 1225, 1229, 1234, 1244, and 1247.

This code is used in section 1099.

1111.   The processing of things like \hskip and \vskip is slightly more complicated. But the code in *main_control* is very short, since it simply calls on the action routine *append_glue*. Similarly, \kern activates *append_kern*.

⟨ Cases of *main_control* that build boxes and lists 1110 ⟩ +≡
vmode + *vskip*, *hmode* + *hskip*, *mmode* + *hskip*, *mmode* + *mskip*: *append_glue*;
any_mode(*kern*), *mmode* + *mkern*: *append_kern*;

1112.   The *hskip* and *vskip* command codes are used for control sequences like \hss and \vfil as well as for \hskip and \vskip. The difference is in the value of *cur_chr*.

    define *fil_code* = 0   { identifies \hfil and \vfil }
    define *fill_code* = 1   { identifies \hfill and \vfill }
    define *ss_code* = 2   { identifies \hss and \vss }
    define *fil_neg_code* = 3   { identifies \hfilneg and \vfilneg }
    define *skip_code* = 4   { identifies \hskip and \vskip }
    define *mskip_code* = 5   { identifies \mskip }

⟨ Put each of TEX's primitives into the hash table 252 ⟩ +≡

kern: *print_esc*("kern");
mkern: *print_esc*("mkern");

1114. All the work relating to glue creation has been relegated to the following subroutine. It does not call *build_page*, because it is used in at least one place where that would be a mistake.

⟨Declare action procedures for use by *main_control* 1097⟩ +≡
procedure *append_glue*;
  var *s*: *small_number*;   {modifier of skip command}
  begin *s* ← *cur_chr*;
  case *s* **of**
  fil_code: *cur_val* ← *fil_glue*;
  fill_code: *cur_val* ← *fill_glue*;
  ss_code: *cur_val* ← *ss_glue*;
  fil_neg_code: *cur_val* ← *fil_neg_glue*;
  skip_code: *scan_glue*(*glue_val*);
  mskip_code: *scan_glue*(*mu_val*);
  end;   {now *cur_val* points to the glue specification}
  tail_append(*new_glue*(*cur_val*));
  if *s* ≥ *skip_code* **then**
    begin *decr*(*glue_ref_count*(*cur_val*));
    if *s* > *skip_code* **then** *subtype*(*tail*) ← *mu_glue*;
    end;
  end;

1115. ⟨Declare action procedures for use by *main_control* 1097⟩ +≡
procedure *append_kern*;
  var *s*: *quarterword*;   {*subtype* of the kern node}
  begin *s* ← *cur_chr*; *scan_dimen*(*s* = *mu_glue*, *false*, *false*); *tail_append*(*new_kern*(*cur_val*));
  subtype(*tail*) ← *s*;
  end;

1116. Many of the actions related to box-making are triggered by the appearance of braces in the input. For example, when the user says '\hbox to 100pt{⟨hlist⟩}' in vertical mode, the information about the box size (100pt, *exactly*) is put onto *save_stack* with a level boundary word just above it, and *cur_group* ← *adjusted_hbox_group*; T𝔼X enters restricted horizontal mode to process the hlist. The right brace eventually causes *save_stack* to be restored to its former state, at which time the information about the box size (100pt, *exactly*) is available once again; a box is packaged and we leave restricted horizontal mode, appending the new box to the current list of the enclosing mode (in this case to the current list of vertical mode), followed by any vertical adjustments that were removed from the box by *hpack*.

The next few sections of the program are therefore concerned with the treatment of left and right curly braces.

1117. If a left brace occurs in the middle of a page or paragraph, it simply introduces a new level of grouping, and the matching right brace will not have such a drastic effect. Such grouping affects neither the mode nor the current list.

⟨Cases of *main_control* that build boxes and lists 1110⟩ +≡
non_math(*left_brace*): *new_save_level*(*simple_group*);
any_mode(*begin_group*): *new_save_level*(*semi_simple_group*);
any_mode(*end_group*): **if** *cur_group* = *semi_simple_group* **then** *unsave*
  else *off_save*;

1118. We have to deal with errors in which braces and such things are not properly nested. Sometimes the user makes an error of commission by inserting an extra symbol, but sometimes the user makes an error of omission. T𝔼X can't always tell one from the other, so it makes a guess and tries to avoid getting into a loop.

The *off_save* routine is called when the current group code is wrong. It tries to insert something into the user's input that will help clean off the top level.

⟨Declare action procedures for use by *main_control* 1097⟩ +≡
procedure *off_save*;
  var *p*: *pointer*;   {inserted token}
  begin if *cur_group* = *bottom_level* **then** ⟨Drop current token and complain that it was unmatched 1120⟩
  else begin *back_input*; *p* ← *get_avail*; *link*(*temp_head*) ← *p*; *print_err*("Missing␣");
    ⟨Prepare to insert a token that matches *cur_group*, and print what it is 1119⟩;
    print("␣inserted"); *ins_list*(*link*(*temp_head*));
    help5("I´ve␣inserted␣something␣that␣you␣may␣have␣forgotten.")
    ("(See␣the␣<inserted␣text>␣above.)")
    ("With␣luck,␣this␣will␣get␣me␣unwedged.␣But␣if␣you")
    ("really␣didn´t␣forget␣anything,␣try␣typing␣`2´␣now;␣then")
    ("my␣insertion␣and␣my␣current␣dilemma␣will␣both␣disappear."); *error*;
    end;
  end;

1119. At this point, *link*(*temp_head*) = *p*, a pointer to an empty one-word node.

⟨ Prepare to insert a token that matches *cur_group*, and print what it is 1119 ⟩ ≡
  case *cur_group* **of**
  semi_simple_group: **begin** *info*(*p*) ← *cs_token_flag* + *frozen_end_group*; *print_esc*("endgroup");

    end;
  math_left_group: **begin** *info*(*p*) ← *cs_token_flag* + *frozen_right*; *link*(*p*) ← *get_avail*; *p* ← *link*(*p*);
    info(*p*) ← *other_token* + "."; *print_esc*("right.");
    end;
  othercases begin *info*(*p*) ← *right_brace_token* + "}"; *print_char*("}");
    end
  endcases

This code is used in section 1118.

1120. ⟨ Drop current token and complain that it was unmatched 1120 ⟩ ≡
  begin *print_err*("Extra␣"); *print_cmd_chr*(*cur_cmd*, *cur_chr*);
  help1("Things␣are␣pretty␣mixed␣up,␣but␣I␣think␣the␣worst␣is␣over.");
  error;
  end

This code is used in section 1118.

1121. The routine for a *right_brace* character branches into many subcases, since a variety of things may happen, depending on *cur_group*. Some types of groups are not supposed to be ended by a right brace; error messages are given in hopes of pinpointing the problem. Most branches of this routine will be filled in later, when we are ready to understand them; meanwhile, we must prepare ourselves to deal with such errors.

⟨ Cases of *main_control* that build boxes and lists 1110 ⟩ +≡
any_mode(*right_brace*): *handle_right_brace*;

1122. ⟨ Declare the procedure called *handle_right_brace* 1122 ⟩ ≡

  end;

1124. Here is where we clear the parameters that are supposed to revert to their default values after every paragraph and when internal vertical mode is entered.

⟨Declare action procedures for use by *main_control* 1097⟩ +≡
procedure *normal_paragraph*;
  begin if *looseness* ≠ 0 **then** *eq_word_define*(*int_base* + *looseness_code*, 0);
  if *hang_indent* ≠ 0 **then** *eq_word_define*(*dimen_base* + *hang_indent_code*, 0);
  if *hang_after* ≠ 1 **then** *eq_word_define*(*int_base* + *hang_after_code*, 1);
  if *par_shape_ptr* ≠ *null* **then** *eq_define*(*par_shape_loc*, *shape_ref*, *null*);
  if *inter_line_penalties_ptr* ≠ *null* **then** *eq_define*(*inter_line_penalties_loc*, *shape_ref*, *null*);
  end;

1125.   Now let's turn to the question of how \hbox is treated. We actually need to consider also
a slightly larger context, since constructions like '\setbox3=\hbox...' and '\leaders\hbox...' and
'\lower3.8pt\hbox...' are supposed to invoke quite different actions after the box has been packaged.
Conversely, constructions like '\setbox3=' can be followed by a variety of different kinds of boxes, and we
would like to encode such things in an efficient way.

In other words, there are two problems: to represent the context of a box, and to represent its type.

The first problem is solved by putting a "context code" on the *save_stack*, just below the two entries
that give the dimensions produced by *scan_spec*. The context code is either a (signed) shift amount,
or it is a large integer $\geq$ *box_flag*, where *box_flag* $= 2^{30}$. Codes *box_flag* through *global_box_flag* $- 1$
represent '\setbox0' through '\setbox32767'; codes *global_box_flag* through *ship_out_flag* $- 1$ represent
'\global\setbox0' through '\global\setbox32767'; code *ship_out_flag* represents '\shipout'; and codes
leader_flag through *leader_flag* $+ 2$ represent '\leaders', '\cleaders', and '\xleaders'.

The second problem is solved by giving the command code *make_box* to all control sequences that produce
a box, and by using the following *chr_code* values to distinguish between them: *box_code*, *copy_code*,
last_box_code, *vsplit_code*, *vtop_code*, *vtop_code* $+$ *vmode*, and *vtop_code* $+$ *hmode*, where the latter two are
used to denote \vbox and \hbox, respectively.

> **define** *box_flag* $\equiv$ ´10000000000   { context code for '\setbox0' }
> **define** *global_box_flag* $\equiv$ ´10000100000   { context code for '\global\setbox0' }
> **define** *ship_out_flag* $\equiv$ ´10000200000   { context code for '\shipout' }

    else $p \leftarrow par\_shape\_ptr + 2 * (prev\_graf + 2)$;
    $s \leftarrow mem[p - 1].sc$; $l \leftarrow mem[p].sc$;
    end

This code is used in section 1199.

1204. Subformulas of math formulas cause a new level of math mode to be entered, on the semantic nest as well as the save stack. These subformulas arise in several ways: (1) A left brace by itself indicates the beginning of a subformula that will be put into a box, thereby freezing its glue and preventing line breaks. (2) A subscript or superscript is treated as a subformula if it is not a single character; the same applies to the nucleus of things like \underline. (3) The \left primitive initiates a subformula that will be terminated by a matching \right. The group codes placed on *save_stack* in these three cases are *math_group*, *math_group*, and *math_left_group*, respectively.

Here is the code that handles case (1); the other cases are not quite as trivial, so we shall consider them later.

⟨ Cases of *main_control* that build boxes and lists 1110 ⟩ +≡
$mmode + left\_brace$: **begin** $tail\_append(new\_noad)$; $back\_input$; $scan\_math(nucleus(tail))$;
  end;

1205.   Recall that the *nucleus*, *subscr*, and *supscr* fields in a noad are broken down into subfields called *math_type* and either *info* or (*fam*, *character*). The job of *scan_math* is to figure out what to place in one of these principal fields; it looks at the subformula that comes next in the input, and places an encoding of that subformula into a given word of *mem*.

    ⟨Append the glue or equation number preceding the display 1257⟩;
    ⟨Append the display and perhaps also the equation number 1258⟩;
    ⟨Append the glue or equation number following the display 1259⟩;
    ⟨Flush the prototype box 1554⟩;
    resume_after_display

This code is used in section 1248.

1254.   ⟨Declare action procedures for use by *main_control* 1097⟩ +≡
procedure *resume_after_display*;
    begin if *cur_group* ≠ *math_shift_group* **then** *confusion*("display");
    unsave; *prev_graf* ← *prev_graf* + 3; *push_nest*; *mode* ← *hmode*; *space_factor* ← 1000; *set_cur_lang*;
    clang ← *cur_lang*;
    prev_graf ← (*norm_min*(*left_hyphen_min*) ∗ ´100 + *norm_min*(*right_hyphen_min*)) ∗ ´200000 + *cur_lang*;
    ⟨Scan an optional space 477⟩;
    if *nest_ptr* = 1 **then** *build_page*;
    end;

1255. The user can force the equation number to go on a separate line by causing its width to be zero.

⟨Squeeze the equation as much as possible; if there is an equation number that should go on a separate line
    by itself, set $e \leftarrow 0$ 1255⟩ ≡
  begin if $(e \neq 0) \land ((w - total\_shrink[normal] + q \leq z) \lor$
          $(total\_shrink[fil] \neq 0) \lor (total\_shrink[fill] \neq 0) \lor (total\_shrink[filll] \neq 0))$ **then**
    begin $free\_node(b, box\_node\_size)$; $b \leftarrow hpack(p, z - q, exactly)$;
    end
  else begin $e \leftarrow 0$;
    if $w > z$ **then**
      begin $free\_node(b, box\_node\_size)$; $b \leftarrow hpack(p, z, exactly)$;
      end;
    end;
  $w \leftarrow width(b)$;
  end

This code is used in section 1253.

1256. We try first to center the display without regard to the existence of the equation number. If that
would make it too close (where "too close" means that the space between display and equation number is
less than the width of the equation number), we either center it in the remaining space or move it as far
from the equation number as possible. The latter alternative is taken only if the display begins with glue,
since we assume that the user put glue there to control the spacing precisely.

⟨Determine the displacement, d, of the left edge of the equation, with respect to the line size z, assuming
    that $l = false$ 1256⟩ ≡
  $set\_box\_lr(b)(dlist)$; $d \leftarrow half(z - w)$;
  if $(e > 0) \land (d < 2 * e)$ **then**   { too close }
    begin $d \leftarrow half(z - w - e)$;
    if $p \neq null$ **then**
      if $\neg is\_char\_node(p)$ **then**
        if $type(p) = glue\_node$ **then** $d \leftarrow 0$;
    end

This code is used in section 1253.

1257. If the equation number is set on a line by itself, either before or after the formula, we append an
infinite penalty so that no page break will separate the display from its number; and we use the same size
and displacement for all three potential lines of the display, even though '\parshape' may specify them
differently.

⟨Append the glue or equation number preceding the display 1257⟩ ≡
  $tail\_append(new\_penalty(pre\_display\_penalty))$;
  if $(d + s \leq pre\_display\_size) \lor l$ **then**   { not enough clearance }
    begin $g1 \leftarrow above\_display\_skip\_code$; $g2 \leftarrow below\_display\_skip\_code$;
    end
  else begin $g1 \leftarrow above\_display\_short\_skip\_code$; $g2 \leftarrow below\_display\_short\_skip\_code$;
    end;
  if $l \land (e = 0)$ **then**   { it follows that $type(a) = hlist\_node$ }

  $tail\_append(new\_penalty(post\_display\_penalty))$; $tail\_append(new\_param\_glue(below\_display\_skip\_code))$;
  $prev\_depth \leftarrow aux\_save.sc$; $resume\_after\_display$;
  end
This code is used in section 860.

1261. ⟨Pontificate about improper alignment in display 1261⟩ ≡
  begin $print\_err($"Missing␣$$␣inserted"$)$;
  $help2($"Displays␣can␣use␣special␣alignments␣(like␣\eqalignno)"$)
  ($"only␣if␣nothing␣but␣the␣alignment␣itself␣is␣between␣$$´s."$)$; $back\_error$;
  end
This code is used in section 1260.

1262.   Mode-independent processing.   The long *main_control* procedure has now been fully specified, except for certain activities that are independent of the current mode. These activities do not change the current vlist or hlist or mlist; if they change anything, it is the value of a parameter or the meaning of a control sequence.

Assignments to values in *eqtb* can be global or local. Furthermore, a control sequence can be defined to be '\long', '\protected', or '\outer', and it might or might not be expanded. The prefixes '\global', '\long', '\protected', and '\outer' can occur in any order. Therefore we assign binary numeric codes, making it possible to accumulate the union of all specified prefixes by adding the corresponding codes. (Pascal's **set** operations could also have been used.)

⟨Put each of T$_{E}$X's primitives into the hash table 252⟩ +≡
  primitive("long", *prefix*, 1); *primitive*("outer", *prefix*, 2); *primitive*("global", *prefix*, 4);
  primitive("def", *def*, 0); *primitive*("gdef", *def*, 1); *primitive*("edef", *def*, 2); *primitive*("xdef", *def*, 3);

**1263.   ** ⟨Cases of *print_cmd_chr* for symbolic printing of primitives 253⟩ +≡
prefix: **if** *chr_code* = 1 **then** *print_esc*("long")
  else if *chr_code* = 2 **then** *print_esc*("outer")

1353.   Dumping and undumping the tables.   After INITEX has seen a collection of fonts and macros, it can write all the necessary information on an auxiliary file so that production versions of TEX are able to initialize their memory at high speed. The present section of the program takes care of such output and input. We shall consider simultaneously the processes of storing and restoring, so that the inverse relation between them is clear.

The global variable *format_ident* is a string that is printed right after the *banner* line when TEX is ready to start. For INITEX this string says simply ' (INITEX)'; for other versions of TEX it says, for example, ' (preloaded format=plain 1982.11.19)', showing the year, month, and day that the format file was created. We have *format_ident* = 0 before TEX's tables are loaded.

⟨ Global variables 13 ⟩ +≡
format_ident: *str_number*;

1354.   ⟨ Set initial values of key variables 23 ⟩ +≡
  format_ident ← 0;

1355.   ⟨ Initialize table entries (done by INITEX only) 189 ⟩ +≡
  format_ident ← "␣(INITEX)";

1356.   ⟨ Declare action procedures for use by *main_control* 1097 ⟩ +≡
  init procedure *store_fmt_file*;
  label *found1*, *found2*, *done1*, *done2*;
  var *j*, *k*, *l*: *integer*;   { all-purpose indices }
    p, *q*: *pointer*;   { all-purpose pointers }
    x: *integer*;   { something to dump }
    w: *four_quarters*;   { four ASCII codes }
  begin ⟨ If dumping is not allowed, abort 1358 ⟩;
  ⟨ Create the *format_ident*, open the format file, and inform the user that dumping has begun 1382 ⟩;
  ⟨ Dump constants for consistency check 1361 ⟩;
  ⟨ Dump the string pool 1363 ⟩;
  ⟨ Dump the dynamic memory 1365 ⟩;
  ⟨ Dump the table of equivalents 1367 ⟩;
  ⟨ Dump the font information 1374 ⟩;
  ⟨ Dump the hyphenation tables 1378 ⟩;
  ⟨ Dump a couple more things and the closing check word 1380 ⟩;
  ⟨ Close the format file 1383 ⟩;
  end;
  tini

1357.   Corresponding to the procedure that dumps a format file, we have a function that reads one in. The function returns *false* if the dumped format is incompatible with the present T$_{E}$X table sizes, etc.

> **define** *bad_fmt* = 6666   { go here if the format file is unacceptable }
> **define** *too_small*(#) ≡
>   **begin** *wake_up_terminal*; *wterm_ln*(´−−−!␣Must␣increase␣the␣´, #); **goto** *bad_fmt*;
>   **end**

⟨ Declare the function called *open_fmt_file* 559 ⟩
function *load_fmt_file*: *boolean*;
  label *bad_fmt*, *exit*;
  var *j*, *k*: *integer*;   { all-purpose indices }
    p, *q*: *pointer*;   { all-purpose pointers }
    x: *integer*;   { something undumped }
    w: *four_quarters*;   { four ASCII codes }
  begin ⟨ Undump constants for consistency check 1362 ⟩;
  ⟨ Undump the string pool 1364 ⟩;
  ⟨ Undump the dynamic memory 1366 ⟩;
  ⟨ Undump the table of equivalents 1368 ⟩;
  ⟨ Undump the font information 1375 ⟩;
  ⟨ Undump the hyphenation tables 1379 ⟩;
  ⟨ Undump a couple more things and the closing check word 1381 ⟩;
  load_fmt_file ← *true*; **return**;   { it worked! }
bad_fmt: *wake_up_terminal*; *wterm_ln*(´(Fatal␣format␣file␣error;␣I´´m␣stymied)´);
  load_fmt_file ← *false*;
exit: **end**;

1358.   The user is not allowed to dump a format file unless *save_ptr* = 0. This condition implies that *cur_level* = *level_one*, hence the *xeq_level* array is constant and it need not be dumped.

⟨ If dumping is not allowed, abort 1358 ⟩ ≡
  if *save_ptr* ≠ 0 **then**
    begin *print_err*("You␣can´t␣dump␣inside␣a␣group"); *help1*("`{...\dump}´␣is␣a␣no-no.");
    succumb;
    end

This code is used in section 1356.

1359.   Format files consist of *memory_word* items, and we use the following macros to dump words of different types:

> **define** *dump_wd*(#) ≡
>   **begin** *fmt_file*↑ ← #; *put*(*fmt_file*); **end**
> **define** *dump_int*(#) ≡
>   **begin** *fmt_file*↑.*int* ← #; *put*(*fmt_file*); **end**
> **define** *dump_hh*(#) ≡
>   **begin** *fmt_file*↑.*hh* ← #; *put*(*fmt_file*); **end**
> **define** *dump_qqqq*(#) ≡
>   **begin** *fmt_file*↑.*qqqq* ← #; *put*(*fmt_file*); **end**

⟨ Global variables 13 ⟩ +≡
fmt_file: *word_file*;   { for input or output of format information }

1360.   The inverse macros are slightly more complicated, since we need to check the range of the values we are reading in. We say '$undump(a)(b)(x)$' to read an integer value x that is supposed to be in the range $a \leq x \leq b$. System error messages should be suppressed when undumping.

define $undump\_wd(\#) \equiv$
           begin $get(fmt\_file)$; $\# \leftarrow fmt\_file\uparrow$; **end**
define $undump\_int(\#) \equiv$
           begin $get(fmt\_file)$; $\# \leftarrow fmt\_file\uparrow.int$; **end**
define $undump\_hh(\#) \equiv$
           begin $get(fmt\_file)$; $\# \leftarrow fmt\_file\uparrow.hh$; **end**
define $undump\_qqqq(\#) \equiv$
           begin $get(fmt\_file)$; $\# \leftarrow fmt\_file\uparrow.qqqq$; **end**
define $undump\_end\_end(\#) \equiv \# \leftarrow x$; **end**
define $undump\_end(\#) \equiv (x > \#)$ **then goto** bad_fmt **else** $undump\_end\_end$
define $undump(\#) \equiv$
         begin $undump\_int(x)$;
         if $(x < \#) \vee undump\_end$
define $undump\_size\_end\_end(\#) \equiv too\_small(\#)$ **else** $undump\_end\_end$
define $undump\_size\_end(\#) \equiv$
           if $x > \#$ **then** $undump\_size\_end\_end$
define $undump\_size(\#) \equiv$
         begin $undump\_int(x)$;
         if $x < \#$ **then goto** bad_fmt;
         $undump\_size\_end$

1361.   The next few sections of the program should make it clear how we use the dump/undump macros.

⟨ Dump constants for consistency check 1361 ⟩ ≡
  $dump\_int(@\$)$;
  ⟨ Dump the ε-T_EX state 1464 ⟩
  $dump\_int(mem\_bot)$;
  $dump\_int(mem\_top)$;
  $dump\_int(eqtb\_size)$;
  $dump\_int(hash\_prime)$;
  $dump\_int(hyph\_size)$

This code is used in section 1356.

1362. Sections of a WEB program that are "commented out" still contribute strings to the string pool; therefore INITEX and TEX will have the same strings. (And it is, of course, a good thing that they do.)

⟨ Undump constants for consistency check 1362 ⟩ ≡
  $x \leftarrow fmt\_file{\uparrow}.int$;
  if $x \neq$ @$ **then goto** bad_fmt;   { check that strings are the same }
  ⟨ Undump the ε-TEX state 1465 ⟩
  $undump\_int(x)$;
  if $x \neq mem\_bot$ **then goto** bad_fmt;
  $undump\_int(x)$;
  if $x \neq mem\_top$ **then goto** bad_fmt;
  $undump\_int(x)$;
  if $x \neq eqtb\_size$ **then goto** bad_fmt;
  $undump\_int(x)$;
  if $x \neq hash\_prime$ **then goto** bad_fmt;
  $undump\_int(x)$;
  if $x \neq hyph\_size$ **then goto** bad_fmt
This code is used in section 1357.

1363.   **define** $dump\_four\_ASCII \equiv w.b0 \leftarrow qi(so(str\_pool[k]))$; $w.b1 \leftarrow qi(so(str\_pool[k+1]))$;
          $w.b2 \leftarrow qi(so(str\_pool[k+2]))$; $w.b3 \leftarrow qi(so(str\_pool[k+3]))$; $dump\_qqqq(w)$

⟨ Dump the string pool 1363 ⟩ ≡
  $dump\_int(pool\_ptr)$; $dump\_int(str\_ptr)$;
  for $k \leftarrow 0$ **to** str_ptr **do** $dump\_int(str\_start[k])$;
  $k \leftarrow 0$;
  while $k + 4 < pool\_ptr$ **do**
    begin $dump\_four\_ASCII$; $k \leftarrow k + 4$;
    end;
  $k \leftarrow pool\_ptr - 4$; $dump\_four\_ASCII$; $print\_ln$; $print\_int(str\_ptr)$;
  $print("_{\sqcup}strings_{\sqcup}of_{\sqcup}total_{\sqcup}length_{\sqcup}")$; $print\_int(pool\_ptr)$
This code is used in section 1356.

1364.   **define** $undump\_four\_ASCII \equiv undump\_qqqq(w)$; $str\_pool[k] \leftarrow si(qo(w.b0))$;
          $str\_pool[k+1] \leftarrow si(qo(w.b1))$; $str\_pool[k+2] \leftarrow si(qo(w.b2))$; $str\_pool[k+3] \leftarrow si(qo(w.b3))$

⟨ Undump the string pool 1364 ⟩ ≡
  $undump\_size(0)(pool\_size)(´string_{\sqcup}pool_{\sqcup}size´)(pool\_ptr)$;
  $undump\_size(0)(max\_strings)(´max_{\sqcup}strings´)(str\_ptr)$;
  for $k \leftarrow 0$ **to** str_ptr **do** $undump(0)(pool\_ptr)(str\_start[k])$;
  $k \leftarrow 0$;
  while $k + 4 < pool\_ptr$ **do**
    begin $undump\_four\_ASCII$; $k \leftarrow k + 4$;
    end;
  $k \leftarrow pool\_ptr - 4$; $undump\_four\_ASCII$; $init\_str\_ptr \leftarrow str\_ptr$; $init\_pool\_ptr \leftarrow pool\_ptr$
This code is used in section 1357.

1365. By sorting the list of available spaces in the variable-size portion of *mem*, we are usually able to get by without having to dump very much of the dynamic memory.

We recompute *var_used* and *dyn_used*, so that INITEX dumps valid information even when it has not been gathering statistics.

⟨ Dump the dynamic memory 1365 ⟩ ≡
  sort_avail; *var_used* ← 0; *dump_int*(*lo_mem_max*); *dump_int*(*rover*);
  if *eTeX_ex* **then**
    for *k* ← *int_val* **to** *inter_char_val* **do** *dump_int*(*sa_root*[*k*]);
  p ← *mem_bot*; *q* ← *rover*; *x* ← 0;
  repeat for *k* ← *p* **to** *q* + 1 **do** *dump_wd*(*mem*[*k*]);
    x ← *x* + *q* + 2 − *p*; *var_used* ← *var_used* + *q* − *p*; *p* ← *q* + *node_size*(*q*); *q* ← *rlink*(*q*);
  until *q* = *rover*;
  var_used ← *var_used* + *lo_mem_max* − *p*; *dyn_used* ← *mem_end* + 1 − *hi_mem_min*;
  for *k* ← *p* **to** *lo_mem_max* **do** *dump_wd*(*mem*[*k*]);
  x ← *x* + *lo_mem_max* + 1 − *p*; *dump_int*(*hi_mem_min*); *dump_int*(*avail*);
  for *k* ← *hi_mem_min* **to** *mem_end* **do** *dump_wd*(*mem*[*k*]);

This code is used in section 1356.

1384.   The main program.   This is it: the part of TEX that executes all those procedures we have written.

Well—almost. Let's leave space for a few more routines that we may have forgotten.

⟨ Last-minute procedures 1387 ⟩

1385.   We have noted that there are two versions of TEX82. One, called `INITEX`, has to be run first; it initializes everything from scratch, without reading a format file, and it has the capability of dumping a format file. The other one is called '`VIRTEX`'; it is a "virgin" program that needs to input a format file in order to get started. `VIRTEX` typically has more memory capacity than `INITEX`, because it does not need the space consumed by the auxiliary hyphenation tables and the numerous calls on *primitive*, etc.

The `VIRTEX` program cannot read a format file instantaneously, of course; the best implementations therefore allow for production versions of TEX that not only avoid the loading routine for Pascal object code, they also have a format file pre-loaded. This is impossible to do if we stick to standard Pascal; but there is a simple way to fool many systems into avoiding the initialization, as follows: (1) We declare a global integer variable called *ready_already*. The probability is negligible that this variable holds any particular value like 314159 when `VIRTEX` is first loaded.   (2) After we have read in a format file and initialized everything, we set *ready_already* ← 314159.   (3) Soon `VIRTEX` will print '∗', waiting for more input; and at this point we interrupt the program and save its core image in some form that the operating system can reload speedily.   (4) When that core image is activated, the program starts again at the beginning; but now *ready_already* = 314159 and all the other global variables have their initial values too. The former chastity has vanished!

In other words, if we allow ourselves to test the condition *ready_already* = 314159, before *ready_already* has been assigned a value, we can avoid the lengthy initialization. Dirty tricks rarely pay off so handsomely.

On systems that allow such preloading, the standard program called `TeX` should be the one that has `plain` format preloaded, since that agrees with *The TEXbook*. Other versions, e.g., `AmSTeX`, should also be provided for commonly used formats.

⟨ Global variables 13 ⟩ +≡
ready_already: *integer*;   { a sacrifice of purity for economy }

1386.   Now this is really it: TEX starts and ends here.

The initial test involving *ready_already* should be deleted if the Pascal runtime system is smart enough to detect such a "mistake."

> **begin**   { *start_here* }
> *history* ← *fatal_error_stop*;   { in case we quit during initialization }
> *t_open_out*;   { open the terminal for output }
> **if** *ready_already* = 314159 **then goto** *start_of_TEX*;
> ⟨ Check the "constant" values for consistency 14 ⟩
> **if** *bad* > 0 **then**
> > **begin** *wterm_ln*(´Ouch---my␣internal␣constants␣have␣been␣clobbered!´, ´---case␣´, *bad* : 1);
> > **goto** *final_end*;
> > **end**;
> *initialize*;   { set global variables to their starting values }
> **init if** ¬*get_strings_started* **then goto** *final_end*;
> *init_prim*;   { call *primitive* for each primitive }
> *init_str_ptr* ← *str_ptr*; *init_pool_ptr* ← *pool_ptr*; *fix_date_and_time*;
> **tini**
> *ready_already* ← 314159;
> *start_of_TEX*: ⟨ Initialize the output routines 55 ⟩;

> *history* ← *spotless*;   { ready to go! }
> *main_control*;   { come to life }
> *final_cleanup*;   { prepare for death }
> *end_of_TEX*: *close_files_and_terminate*;
> *final_end*: *ready_already* ← 0;
> **end**.

1387.   Here we do whatever is needed to complete TEX's job gracefully on the local operating system. The code here might come into play after a fatal error; it must therefore consist entirely of "safe" operations that cannot produce error messages. For example, it would be a mistake to call *str_room* or *make_string* at this time, because a call on *overflow* might lead to an infinite loop. (Actually there's one way to get error messages, via *prepare_mag*; but that can't cause infinite recursion.)

If *final_cleanup* is bypassed, this program doesn't bother to close the input files that may still be open.

⟨ Last-minute procedures 1387 ⟩ ≡

  end

This code is used in section 1386.

1392. Debugging.   Once TEX is working, you should be able to diagnose most errors with the \show commands and other diagnostic features. But for the initial stages of debugging, and for the revelation of really deep mysteries, you can compile TEX with a few more aids, including the Pascal runtime checks and its debugger. An additional routine called *debug_help* will also come into play when you type 'D' after an error message; *debug_help* also occurs just before a fatal error causes TEX to succumb.

The interface to *debug_help* is primitive, but it is good enough when used with a Pascal debugger that allows you to set breakpoints and to read variables and change their values. After getting the prompt 'debug #', you type either a negative number (this exits *debug_help*), or zero (this goes to a location where you can set a breakpoint, thereby entering into dialog with the Pascal debugger), or a positive number m followed by an argument n. The meaning of m and n will be clear from the program below. (If $m = 13$, there is an additional argument, l.)

define *breakpoint* = 888   { place where a breakpoint is desirable }

⟨ Last-minute procedures 1387 ⟩ +≡
  debug procedure *debug_help*;   { routine to display various things }
  label *breakpoint*, *exit*;
  var k, l, m, n: *integer*;
  begin *clear_terminal*;
  loop
    begin *wake_up_terminal*; *print_nl*("debug␣#␣(−1␣to␣exit):"); *update_terminal*; *read*(*term_in*, *m*);
    if $m < 0$ **then return**
    else if $m = 0$ **then**
        begin goto *breakpoint*;
          { go to every declared label at least once }
      breakpoint: $m \leftarrow 0$; @{´BREAKPOINT´@}
        end
      else begin *read*(*term_in*, *n*);
        case m **of**
        ⟨ Numbered cases for *debug_help* 1393 ⟩

  end;

16: *panicking* ← ¬*panicking*;

This code is used in section 1392.

1394.   Extensions.   The program above includes a bunch of "hooks" that allow further capabilities to be added without upsetting TEX's basic structure. Most of these hooks are concerned with "whatsit" nodes, which are intended to be used for special purposes; whenever a new extension to TEX involves a new kind of whatsit node, a corresponding change needs to be made to the routines below that deal with such nodes, but it will usually be unnecessary to make many changes to the other parts of this program.

In order to demonstrate how extensions can be made, we shall treat '\write', '\openout', '\closeout', '\immediate', '\special', and '\setlanguage' as if they were extensions. These commands are actually primitives of TEX, and they should appear in all implementations of the system; but let's try to imagine that they aren't. Then the program below illustrates how a person could add them.

Sometimes, of course, an extension will require changes to TEX itself; no system of hooks could be complete enough for all conceivable extensions. The features associated with '\write' are almost all confined to the following paragraphs, but there are small parts of the *print_ln* and *print_char* procedures that were introduced specifically to \write characters. Furthermore one of the token lists recognized by the scanner is a *write_text*; and there are a few other miscellaneous places where we have already provided for some aspect of \write. The goal of a TEX extender should be to minimize alterations to the standard parts of the program, and to avoid them completely if possible. He or she should also be quite sure that there's no easy way to accomplish the desired goals with the standard features that TEX already has. "Think thrice before extending," because that may save a lot of work, and it will also keep incompatible extensions of TEX from proliferating.

1395.   First let's consider the format of whatsit nodes that are used to represent the data associated with \write and its relatives. Recall that a whatsit has $type = whatsit\_node$, and the *subtype* is supposed to distinguish different kinds of whatsits. Each node occupies two or more words; the exact number is immaterial, as long as it is readily determined from the *subtype* or other data.

We shall introduce five *subtype* values here, corresponding to the control sequences \openout, \write, \closeout, \special, and \setlanguage. The second word of I/O whatsits has a *write_stream* field that identifies the write-stream number (0 to 15, or 16 for out-of-range and positive, or 17 for out-of-range and negative). In the case of \write and \special, there is also a field that points to the reference count of a token list that should be sent. In the case of \openout, we need three words and three auxiliary subfields to hold the string numbers for name, area, and extension.

> **define** *write_node_size* = 2   { number of words in a write/whatsit node }
> **define** *open_node_size* = 3   { number of words in an open/whatsit node }
> **define** *open_node* = 0   { *subtype* in whatsits that represent files to \openout }
> **define** *write_node* = 1   { *subtype* in whatsits that represent things to \write }
> **define** *close_node* = 2   { *subtype* in whatsits that represent streams to \closeout }
> **define** *special_node* = 3   { *subtype* in whatsits that represent \special things }
> **define** *latespecial_node* = 4   { *subtype* in whatsits that represent \special things }
> **define** *language_node* = 5   { *subtype* in whatsits that change the current language }
> **define** *what_lang*(#) ≡ *link*(# + 1)   { language number, in the range 0 . . 255 }
> **define** *what_lhm*(#) ≡ *type*(# + 1)   { minimum left fragment, in the range 1 . . 63 }
> **define** *what_rhm*(#) ≡ *subtype*(# + 1)   { minimum right fragment, in the range 1 . . 63 }
> **define** *write_tokens*(#) ≡ *link*(# + 1)   { reference count of token list to write }
> **define** *write_stream*(#) ≡ *info*(# + 1)   { stream number (0 to 17) }
> **define** *open_name*(#) ≡ *link*(# + 1)   { string number of file name to open }
> **define** *open_area*(#) ≡ *info*(# + 2)   { string number of file area for *open_name* }
> **define** *open_ext*(#) ≡ *link*(# + 2)   { string number of file extension for *open_name* }

1396. The sixteen possible \write streams are represented by the *write_file* array. The *j*th file is open if and only if *write_open*[*j*] = *true*. The last two streams are special; *write_open*[16] represents a stream number greater than 15, while *write_open*[17] represents a negative stream number, and both of these variables are always *false*.

⟨Global variables 13⟩ +≡

 if *subtype*(*p*) = *latespecial_node* **then** *flush_list*(*def_ref*);
 doing_special ← *false*;
 end;

See also sections 1433, 1436, 1529, and 1533.

This code is used in section 655.

1432.   To write a token list, we must run it through TEX's scanner, expanding macros and `\the` and `\number`, etc. This might cause runaways, if a delimited macro parameter isn't matched, and runaways would be extremely confusing since we are calling on TEX's scanner in the middle of a `\shipout` command. Therefore we will put a dummy control sequence as a "stopper," right after the token list. This control sequence is artificially defined to be `\outer`.

⟨Initialize table entries (done by INITEX only) 189⟩ +≡
 text(*end_write*) ← "endwrite"; *eq_level*(*end_write*) ← *level_one*; *eq_type*(*end_write*) ← *outer_call*;
 equiv(*end_write*) ← *null*;

1433. ⟨Declare procedures needed in *hlist_out*, *vlist_out* 1431⟩ +≡
procedure *write_out*(*p* : *pointer*);
  var *old_setting*: 0 . . *max_selector*;   {holds print *selector*}
    old_mode: *integer*;   {saved *mode*}
    j: *small_number*;   {write stream number}
    k: *integer*; *q*, *r*: *pointer*;   {temporary variables for list manipulation}
  begin ⟨Expand macros in the token list and make *link*(*def_ref*) point to the result 1434⟩;
  old_setting ← *selector*; *j* ← *write_stream*(*p*);
  if *write_open*[*j*] **then** *selector* ← *j*
  else begin   {write to the terminal if file isn't open}
    if (*j* = 17) ∧ (*selector* = *term_and_log*) **then** *selector* ← *log_only*;
    print_nl("");
    end;
  token_show(*def_ref*); *print_ln*; *flush_list*(*def_ref*); *selector* ← *old_setting*;
  end;

1434. The final line of this routine is slightly subtle; at least, the author didn't think about it until getting burnt! There is a used-up token list on the stack, namely the one that contained *end_write_token*. (We insert this artificial '\endwrite' to prevent runaways, as explained above.) If it were not removed, and if there were numerous writes on a single page, the stack would overflow.

  define *end_write_token* ≡ *cs_token_flag* + *end_write*

⟨Expand macros in the token list and make *link*(*def_ref*) point to the result 1434⟩ ≡
  q ← *get_avail*; *info*(*q*) ← *right_brace_token* + "}";

1451.   The extended features of ε-TEX.   The program has two modes of operation: (1) In TEX compatibility mode it fully deserves the name TEX and there are neither extended features nor additional primitive commands. There are, however, a few modifications that would be legitimate in any implementation of TEX such as, e.g., preventing inadequate results of the glue to DVI unit conversion during *ship_out*. (2) In extended mode there are additional primitive commands and the extended features of ε-TEX are available.

The distinction between these two modes of operation initially takes place when a 'virgin' eINITEX starts without reading a format file. Later on the values of all ε-TEX state variables are inherited when eVIRTEX (or eINITEX) reads a format file.

The code below is designed to work for cases where '**init** ... **tini**' is a run-time switch.

⟨ Enable ε-TEX, if requested 1451 ⟩ ≡
   init if (*buffer*[*loc*] = "*") ∧ (*format_ident* = "␣(INITEX)") **then**
      begin *no_new_control_sequence* ← *false*; ⟨ Generate all ε-TEX primitives 1399 ⟩
      incr(*loc*); *eTeX_mode* ← 1; { enter extended mode }
      ⟨ Initialize variables for ε-TEX extended mode 1624 ⟩
      end;
   tini
   if ¬*no_new_control_sequence* **then**   { just entered extended mode ? }
      no_new_control_sequence ← *true* **else**

This code is used in section 1391.

1452.   The ε-TEX features available in extended mode are grouped into two categories: (1) Some of them are permanently enabled and have no semantic effect as long as none of the additional primitives are executed. (2) The remaining ε-TEX features are optional and can be individually enabled and disabled. For each optional feature there is an ε-TEX state variable named `\...state`; the feature is enabled, resp. disabled by assigning a positive, resp. non-positive value to that integer.

This code is used in section 1243.

1509.   In constructions such as

```
\hbox to \hsize{
    \hskip 0pt plus 0.0001fil
    ...
    \hfil\penalty-200\hfilneg
    ...}
```

the stretch components of \hfil and \hfilneg compensate; they may, however, get modified in order to prevent arithmetic overflow during *hlist_out* when each of them is multiplied by a large *glue_set* value.

Since this "glue rounding" depends on state variables *cur_g* and *cur_glue* and TEX--X∃T is supposed to emulate the behaviour of TEX-X∃T (plus a suitable postprocessor) as close as possible the glue rounding cannot be postponed until (segments of) an hlist has been reversed.

The code below is invoked after the effective width, *rule_wd*, of a glue node has been computed. The glue node is either converted into a kern node or, for leaders, the glue specification is replaced by an equivalent rigid one; the subtype of the glue node remains unchanged.

⟨Handle a glue node for mixed direction typesetting 1509⟩ ≡
  if $(((g\_sign = stretching) \wedge (stretch\_order(g) = g\_order)) \vee ((g\_sign = shrinking) \wedge (shrink\_order(g) = g\_order)))$ **then**
    begin *fast_delete_glue_ref*(g);
    if *subtype*(p) < *a_leaders* **then**
      begin *type*(p) ← *kern_node*; *width*(p) ← *rule_wd*;
      end
    else begin g ← *get_node*(*glue_spec_size*);
      stretch_order(g) ← *filll* + 1; *shrink_order*(g) ← *filll* + 1;   { will never match }
      width(g) ← *rule_wd*; *stretch*(g) ← 0; *shrink*(g) ← 0; *glue_ptr*(p) ← g;
      end;
    end

This code is used in sections 663 and 1537.

1510.   The optional *TeXXeT* feature of ε-TEX contains the code for mixed left-to-right and right-to-left typesetting. This code is inspired by but different from TEX-X$_{\mathcal{E}}$T as presented by Donald E. Knuth and Pierre MacKay in *TUGboat* **8**, 14–25, 1987.

In order to avoid confusion with TEX-X$_{\mathcal{E}}$T the present implementation of mixed direction typesetting is called TEX--X$_{\mathcal{E}}$T. It differs from TEX-X$_{\mathcal{E}}$T in several important aspects: (1) Right-to-left text is reversed explicitly by the *ship_out* routine and is written to a normal DVI file without any *begin_reflect* or *end_reflect* commands; (2) a *math_node* is (ab)used instead of a *whatsit_node* to record the \beginL, \endL, \beginR, and \endR text direction primitives in order to keep the influence on the line breaking algorithm for pure left-to-right text as small as possible; (3) right-to-left text interrupted by a displayed equation is automatically resumed after that equation; and (4) the *valign* command code with a non-zero command modifier is (ab)used for the text direction primitives.

Nevertheless there is a subtle difference between TEX and TEX--X$_{\mathcal{E}}$T that may influence the line breaking algorithm for pure left-to-right text. When a paragraph containing math mode material is broken into lines TEX may generate lines where math mode material is not enclosed by properly nested \mathon and \mathoff nodes. Unboxing such lines as part of a new paragraph may have the effect that hyphenation is attempted for 'words' originating from math mode or that hyphenation is inhibited for words originating from horizontal mode.

In TEX--X$_{\mathcal{E}}$T additional \beginM, resp. \endM math nodes are supplied at the start, resp. end of lines such that math mode material inside a horizontal list always starts with either \mathon or \beginM and ends with \mathoff or \endM. These additional nodes are transparent to operations such as \unskip, \lastpenalty, or \lastbox but they do have the effect that hyphenation is never attempted for 'words' originating from math mode and is never inhibited for words originating from horizontal mode.

This code is used in section 1526.

1528. ⟨Check for LR anomalies at the end of *hlist_out* 1528⟩ ≡
  begin while *info*(*LR_ptr*) ≠ *before* **do**
    begin if *info*(*LR_ptr*) > *L_code* **then** *LR_problems* ← *LR_problems* + 10000;
    pop_LR;
    end;
  pop_LR;
  end

This code is used in section 1525.

1529.   **define** $edge\_node = style\_node$ { a $style\_node$ does not occur in hlists }
   define $edge\_node\_size = style\_node\_size$ { number of words in an edge node }
   define $edge\_dist(\#) \equiv depth(\#)$
            { new $left\_edge$ position relative to cur_h (after $width$ has been taken into account) }

⟨ Declare procedures needed in $hlist\_out$, $vlist\_out$ 1431 ⟩ +≡
function $new\_edge(s : small\_number; w : scaled): pointer;$ { create an edge node }
   var p: $pointer$;   { the new node }
   begin $p \leftarrow get\_node(edge\_node\_size);$ $type(p) \leftarrow edge\_node;$ $subtype(p) \leftarrow s;$ $width(p) \leftarrow w;$
   $edge\_dist(p) \leftarrow 0;$ { the $edge\_dist$ field will be set later }
   $new\_edge \leftarrow p;$
   end;

1530.   ⟨ Cases of $hlist\_out$ that arise in mixed direction text only 1530 ⟩ ≡
$edge\_node:$ **begin** $cur\_h \leftarrow cur\_h + width(p);$ $left\_edge \leftarrow cur\_h + edge\_dist(p);$ $cur\_dir \leftarrow subtype(p);$
   end;

This code is used in section 660.

1531.   We detach the hlist, start a new one consisting of just one kern node, append the reversed list, and
set the width of the kern node.

⟨ Reverse the complete hlist and set the subtype to $reversed$ 1531 ⟩ ≡
   begin $save\_h \leftarrow cur\_h;$ $temp\_ptr \leftarrow p;$ $p \leftarrow new\_kern(0);$ $link(prev\_p) \leftarrow p;$ $cur\_h \leftarrow 0;$
   $link(p) \leftarrow reverse(this\_box, null, cur\_g, cur\_glue);$ $width(p) \leftarrow -cur\_h;$ $cur\_h \leftarrow save\_h;$
   $set\_box\_lr(this\_box)(reversed);$
   end

This code is used in section 1524.

1532.   We detach the remainder of the hlist, replace the math node by an edge node, and append the
reversed hlist segment to it; the tail of the reversed segment is another edge node and the remainder of the
original list is attached to it.

⟨ Reverse an hlist segment and **goto** $reswitch$ 1532 ⟩ ≡
   begin $save\_h \leftarrow cur\_h;$ $temp\_ptr \leftarrow link(p);$ $rule\_wd \leftarrow width(p);$ $free\_node(p, small\_node\_size);$
   $cur\_dir \leftarrow reflected;$ $p \leftarrow new\_edge(cur\_dir, rule\_wd);$ $link(prev\_p) \leftarrow p;$
   $cur\_h \leftarrow cur\_h - left\_edge + rule\_wd;$ $link(p) \leftarrow reverse(this\_box, new\_edge(reflected, 0), cur\_g, cur\_glue);$
   $edge\_dist(p) \leftarrow cur\_h;$ $cur\_dir \leftarrow reflected;$ $cur\_h \leftarrow save\_h;$ **goto** $reswitch;$
   end

This code is used in section 1527.

1533.   The *reverse* function defined here is responsible to reverse the nodes of an hlist (segment). The first parameter *this_box* is the enclosing hlist node, the second parameter t is to become the tail of the reversed list, and the global variable *temp_ptr* is the head of the list to be reversed. Finally *cur_g* and *cur_glue* are the current glue rounding state variables, to be updated by this function. We remove nodes from the original list and add them to the head of the new one.

⟨ Declare procedures needed in *hlist_out*, *vlist_out* 1431 ⟩ +≡

      end
    else begin *type*(*p*) ← *kern_node*; *incr*(*m*);
      end;
    end
This code is used in section 1549.

1551. The prototype box is an hlist node with the width, glue set, and shift amount of *just_box*, i.e., the last line preceding the display. Its hlist reflects the current \leftskip and \rightskip.

⟨Let *j* be the prototype box for the display 1551⟩ ≡
  begin if *right_skip* = *zero_glue* **then** *j* ← *new_kern*(0)
  else *j* ← *new_param_glue*(*right_skip_code*);
  if *left_skip* = *zero_glue* **then** *p* ← *new_kern*(0)
  else *p* ← *new_param_glue*(*left_skip_code*);
  link(*p*) ← *j*; *j* ← *new_null_box*; *width*(*j*) ← *width*(*just_box*); *shift_amount*(*j*) ← *shift_amount*(*just_box*);
  list_ptr(*j*) ← *p*; *glue_order*(*j*) ← *glue_order*(*just_box*); *glue_sign*(*j*) ← *glue_sign*(*just_box*);
  glue_set(*j*) ← *glue_set*(*just_box*);
  end
This code is used in section 1545.

1552. At the end of a displayed equation we retrieve the prototype box.
⟨Local variables for finishing a displayed formula 1252⟩ +≡
j: *pointer*; {prototype box}

1553. ⟨Retrieve the prototype box 1553⟩ ≡
  if *mode* = *mmode* **then** *j* ← *LR_box*
This code is used in sections 1248 and 1248.

1554. ⟨Flush the prototype box 1554⟩ ≡
  flush_node_list(*j*)
This code is used in section 1253.

1555. The *app_display* procedure used to append the displayed equation and/or equation number to the current vertical list has three parameters: the prototype box, the hbox to be appended, and the displacement of the hbox in the display line.

⟨ Declare subprocedures for *after_math* 1555 ⟩ ≡
procedure *app_display*(*j, b* : *pointer*; *d* : *scaled*);
   var *z*: *scaled*;   { width of the line }
    s: *scaled*;   { move the line right this much }
    e: *scaled*;   { distance from right edge of box to end of line }
    x: *integer*;   { *pre_display_direction* }
    p, q, r, t, u: *pointer*;   { for list manipulation }
   begin *s* ← *display_indent*; *x* ← *pre_display_direction*;
   if *x* = 0 **then** *shift_amount*(*b*) ← *s* + *d*
   else begin *z* ← *display_width*; *p* ← *b*; ⟨ Set up the hlist for the display line 1556 ⟩;
    ⟨ Package the display line 1557 ⟩;
    end;
   append_to_vlist(*b*);
   end;

This code is used in section 1248.

1556. Here we construct the hlist for the display, starting with node *p* and ending with node *q*. We also set *d* and *e* to the amount of kerning to be added before and after the hlist (adjusted for the prototype box).

⟨ Set up the hlist for the display line 1556 ⟩ ≡
   if *x* > 0 **then** *e* ← *z* − *d* − *width*(*p*)
   else begin *e* ← *d*; *d* ← *z* − *e* − *width*(*p*);
    end;
   if *j* ≠ *null* **then**
    begin *b* ← *copy_node_list*(*j*); *height*(*b*) ← *height*(*p*); *depth*(*b*) ← *depth*(*p*); *s* ← *s* − *shift_amount*(*b*);
    d ← *d* + *s*; *e* ← *e* + *width*(*b*) − *z* − *s*;
    end;
   if *box_lr*(*p*) = *dlist* **then** *q* ← *p*   { display or equation number }
   else begin   { display and equation number }
    r ← *list_ptr*(*p*); *free_node*(*p*, *box_node_size*);
    if *r* = *null* **then** *confusion*("LR4");
    if *x* > 0 **then**
     begin *p* ← *r*;
     repeat *q* ← *r*; *r* ← *link*(*r*);   { find tail of list }
     until *r* = *null*;
     end
    else begin *p* ← *null*; *q* ← *r*;
     repeat *t* ← *link*(*r*); *link*(*r*) ← *p*; *p* ← *r*; *r* ← *t*;   { reverse list }
     until *r* = *null*;
     end;
    end

This code is used in section 1555.

1557. In the presence of a prototype box we use its shift amount and width to adjust the values of kerning and add these values to the glue nodes inserted to cancel the \leftskip and \rightskip. If there is no prototype box (because the display is preceded by an empty paragraph), or if the skip parameters are zero, we just add kerns.

The *cancel_glue* macro creates and links a glue node that is, together with another glue node, equivalent to a given amount of kerning. We can use j as temporary pointer, since all we need is $j \neq null$.

define *cancel_glue*(#) ≡ $j \leftarrow new\_skip\_param(\#)$; *cancel_glue_cont*
define *cancel_glue_cont*(#) ≡ $link(\#) \leftarrow j$; *cancel_glue_cont_cont*
define *cancel_glue_cont_cont*(#) ≡ $link(j) \leftarrow \#$; *cancel_glue_end*
define *cancel_glue_end*(#) ≡ $j \leftarrow glue\_ptr(\#)$; *cancel_glue_end_end*
define *cancel_glue_end_end*(#) ≡ $stretch\_order(temp\_ptr) \leftarrow stretch\_order(j)$;
        $shrink\_order(temp\_ptr) \leftarrow shrink\_order(j)$; $width(temp\_ptr) \leftarrow \# - width(j)$;
        $stretch(temp\_ptr) \leftarrow -stretch(j)$; $shrink(temp\_ptr) \leftarrow -shrink(j)$

⟨ Package the display line 1557 ⟩ ≡
  if $j = null$ **then**
    begin $r \leftarrow new\_kern(0)$; $t \leftarrow new\_kern(0)$;   { the widths will be set later }
    end
  else begin $r \leftarrow list\_ptr(b)$; $t \leftarrow link(r)$;
    end;
  $u \leftarrow new\_math(0, end\_M\_code)$;
  if $type(t) = glue\_node$ **then**   { t is \rightskip glue }
    begin *cancel_glue*(*right_skip_code*)(q)(u)(t)(e); $link(u) \leftarrow t$;
    end
  else begin $width(t) \leftarrow e$; $link(t) \leftarrow u$; $link(q) \leftarrow t$;
    end;
  $u \leftarrow new\_math(0, begin\_M\_code)$;
  if $type(r) = glue\_node$ **then**   { r is \leftskip glue }
    begin *cancel_glue*(*left_skip_code*)(u)(p)(r)(d); $link(r) \leftarrow u$;
    end
  else begin $width(r) \leftarrow d$; $link(r) \leftarrow p$; $link(u) \leftarrow r$;
    if $j = null$ **then**
      begin $b \leftarrow hpack(u, natural)$; $shift\_amount(b) \leftarrow s$;
      end
    else $list\_ptr(b) \leftarrow u$;
    end

This code is used in section 1555.

1558. The *scan_tokens* feature of ε-TEX defines the \scantokens primitive.

⟨ Generate all ε-TEX primitives 1399 ⟩ +≡
  $primitive(\texttt{"scantokens"}, input, 2)$;

1559. ⟨ Cases of *input* for *print_cmd_chr* 1559 ⟩ ≡

  flush_list(*n*); *b* ← (*eq_type*(*cur_cs*) ≠ *undefined_cs*); *is_in_csname* ← *e*;
  end;

1579. ⟨ Look up the characters of list *n* in the hash table, and set *cur_cs* 1579 ⟩ ≡
  m ← *first*; *p* ← *link*(*n*);
  while *p* ≠ *null* **do**
    begin if *m* ≥ *max_buf_stack* **then**
      begin *max_buf_stack* ← *m* + 1;
      if *max_buf_stack* = *buf_size* **then** *overflow*("buffer␣size", *buf_size*);
      end;
    buffer[*m*] ← *info*(*p*) **mod** *max_char_val*; *incr*(*m*); *p* ← *link*(*p*);
    end;
  if *m* > *first* + 1 **then** *cur_cs* ← *id_lookup*(*first*, *m* − *first*)   { *no_new_control_sequence* is *true* }
  else if *m* = *first* **then** *cur_cs* ← *null_cs*   { the list is empty }
    else *cur_cs* ← *single_base* + *buffer*[*first*]   { the list has length one }
This code is used in section 1578.

1580. The conditional `\iffontchar` tests the existence of a character in a font.

⟨ Cases for *conditional* 1577 ⟩ +≡
if_in_csname_code: *b* ← *is_in_csname*;
if_font_char_code: **begin** *scan_font_ident*; *n* ← *cur_val*; *scan_usv_num*;
  if *is_native_font*(*n*) **then** *b* ← (*map_char_to_glyph*(*n*, *cur_val*) > 0)
  else begin if (*font_bc*[*n*] ≤ *cur_val*) ∧ (*font_ec*[*n*] ≥ *cur_val*) **then**
      b ← *char_exists*(*char_info*(*n*)(*qi*(*cur_val*)))
    else *b* ← *false*;
    end;
  end;

1581. The *protected* feature of ε-TEX defines the \protected prefix command for macro definitions. Such macros are protected against expansions when lists of expanded tokens are built, e.g., for \edef or during \write.

⟨ Generate all ε-TEX primitives 1399 ⟩ +≡
  primitive("protected", *prefix*, 8);

1582. ⟨ Cases of *prefix* for *print_cmd_chr* 1582 ⟩ ≡
else if *chr_code* = 8 **then** *print_esc*("protected")
This code is used in section 1263.

1583. The *get_x_or_protected* procedure is like *get_x_token* except that protected macros are not expanded.

⟨ Declare ε-TEX procedures for scanning 1492 ⟩ +≡
procedure *get_x_or_protected*;   { sets *cur_cmd*, *cur_chr*, *cur_tok*, and expands non-protected macros }
  label *exit*;
  begin loop begin *get_token*;
    if *cur_cmd* ≤ *max_command* **then return**;
    if (*cur_cmd* ≥ *call*) ∧ (*cur_cmd* < *end_template*) **then**
      if *info*(*link*(*cur_chr*)) = *protected_token* **then return**;
    expand;
    end;
exit: **end**;

1584. A group entered (or a conditional started) in one file may end in a different file. Such slight anomalies, although perfectly legitimate, may cause errors that are difficult to locate. In order to be able to give a warning message when such anomalies occur, ε-TEX uses the *grp_stack* and *if_stack* arrays to record the initial *cur_boundary* and *cond_ptr* values for each input file.

⟨ Global variables 13 ⟩ +≡
grp_stack: **array** [0 . . *max_in_open*] **of** *save_pointer*;   { initial *cur_boundary* }
if_stack: **array** [0 . . *max_in_open*] **of** *pointer*;   { initial *cond_ptr* }

1585.   When a group ends that was apparently entered in a different input file, the *group_warning* procedure is invoked in order to update the *grp_stack*. If moreover \tracingnesting is positive we want to give a warning message. The situation is, however, somewhat complicated by two facts: (1) There may be *grp_stack* elements without a corresponding \input file or \scantokens pseudo file (e.g., error insertions from the terminal); and (2) the relevant information is recorded in the *name_field* of the *input_stack* only loosely synchronized with the *in_open* variable indexing *grp_stack*.

⟨ Declare ε-TEX procedures for tracing and input 314 ⟩ +≡

procedure *group_warning*;
  var *i*: 0 . . *max_in_open*;   { index into *grp_stack* }
    w: *boolean*;   { do we need a warning? }
  begin *base_ptr* ← *input_ptr*; *input_stack*[*base_ptr*] ← *cur_input*;   { store current state }
  i ← *in_open*; *w* ← *false*;
  while (*grp_stack*[*i*] = *cur_boundary*) ∧ (*i* > 0) **do**
    begin ⟨ Set variable *w* to indicate if this case should be reported 1586 ⟩;
    grp_stack[*i*] ← *save_index*(*save_ptr*); *decr*(*i*);
    end;
  if *w* **then**
    begin *print_nl*("Warning:␣end␣of␣"); *print_group*(*true*); *print*("␣of␣a␣different␣file"); *print_ln*;
    if *tracing_nesting* > 1 **then** *show_context*;
    if *history* = *spotless* **then** *history* ← *warning_issued*;
    end;
  end;

1586.   This code scans the input stack in order to determine the type of the current input file.

⟨ Set variable *w* to indicate if this case should be reported 1586 ⟩ ≡
  if *tracing_nesting* > 0 **then**
    begin while (*input_stack*[*base_ptr*].*state_field* = *token_list*) ∨ (*input_stack*[*base_ptr*].*index_field* > *i*) **do**
      decr(*base_ptr*);
    if *input_stack*[*base_ptr*].*name_field* > 17 **then** *w* ← *true*;
    end
This code is used in sections 1585 and 1587.

1587. When a conditional ends that was apparently started in a different input file, the *if_warning* procedure is invoked in order to update the *if_stack*. If moreover \tracingnesting is positive we want to give a warning message (with the same complications as above).

⟨ Declare ε-TEX procedures for tracing and input 314 ⟩ +≡

procedure *if_warning*;
  var *i*: 0 . . *max_in_open*;   { index into *if_stack* }
    w: *boolean*;   { do we need a warning? }
  begin *base_ptr* ← *input_ptr*; *input_stack*[*base_ptr*] ← *cur_input*;   { store current state }
  i ← *in_open*; *w* ← *false*;
  while *if_stack*[*i*] = *cond_ptr* **do**
    begin ⟨ Set variable *w* to indicate if this case should be reported 1586 ⟩;
    if_stack[*i*] ← *link*(*cond_ptr*); *decr*(*i*);
    end;
  if *w* **then**
    begin *print_nl*("Warning:␣end␣of␣"); *print_cmd_chr*(*if_test*, *cur_if*); *print_if_line*(*if_line*);
    print("␣of␣a␣different␣file"); *print_ln*;
    if *tracing_nesting* > 1 **then** *show_context*;
    if *history* = *spotless* **then** *history* ← *warning_issued*;
    end;
  end;

1588. Conversely, the *file_warning* procedure is invoked when a file ends and some groups entered or conditionals started while reading from that file are still incomplete.

⟨ Declare ε-TEX procedures for tracing and input 314 ⟩ +≡

procedure *file_warning*;

   end
This code is used in section 1596.

1600. ⟨Pop the expression stack and **goto** *found* 1600⟩ ≡
   begin $f \leftarrow e$; $q \leftarrow p$; $e \leftarrow$ *expr_e_field*(q); $t \leftarrow$ *expr_t_field*(q); $n \leftarrow$ *expr_n_field*(q); $s \leftarrow$ *subtype*(q) **div** 4;
   $r \leftarrow$ *subtype*(q) **mod** 4; $l \leftarrow$ *type*(q); $p \leftarrow$ *link*(q); *free_node*(q, *expr_node_size*); **goto** *found*;
   end
This code is used in section 1594.

1601.   We want to make sure that each term and (intermediate) result is in the proper range. Integer values must not exceed *infinity* $(2^{31}-1)$ in absolute value, dimensions must not exceed *max_dimen* $(2^{30}-1)$. We avoid the absolute value of an integer, because this might fail for the value -2^{31} using 32-bit arithmetic.

> **define** *num_error*(#) ≡   { clear a number or dimension and set *arith_error* }
>   **begin** *arith_error* ← *true*; # ← 0;
>   **end**
> **define** *glue_error*(#) ≡   { clear a glue spec and set *arith_error* }
>   **begin** *arith_error* ← *true*; *delete_glue_ref*(#); # ← *new_spec*(*zero_glue*);
>   **end**

⟨ Make sure that *f* is in the proper range 1601 ⟩ ≡
  if $(l = int\_val) \vee (s > expr\_sub)$ **then**
    begin if $(f > infinity) \vee (f < -infinity)$ **then** *num_error*(*f*);
    end
  else if $l = dimen\_val$ **then**
      begin if $abs(f) > max\_dimen$ **then** *num_error*(*f*);
      end
    else begin if $(abs(width(f)) > max\_dimen) \vee (abs(stretch(f)) > max\_dimen) \vee$
            $(abs(shrink(f)) > max\_dimen)$ **then** *glue_error*(*f*);
      end
This code is used in section 1594.

1602.   Applying the factor *f* to the partial term *t* (with the operator *s*) is delayed until the next operator *o* has been scanned. Here we handle the first factor of a partial term. A glue spec has to be copied unless the next operator is a right parenthesis; this allows us later on to simply modify the glue components.

> **define** *normalize_glue*(#) ≡
>   **if** *stretch*(#) = 0 **then** *stretch_order*(#) ← *normal*;
>   **if** *shrink*(#) = 0 **then** *shrink_order*(#) ← *normal*

⟨ Cases for evaluation of the current term 1602 ⟩ ≡
expr_none: **if** $(l \geq glue\_val) \wedge (o \neq expr\_none)$ **then**
    begin $t ← new\_spec(f)$; *delete_glue_ref*(*f*); *normalize_glue*(*t*);
    end
  else $t ← f$;
See also sections 1606, 1607, and 1609.
This code is used in section 1594.

1603.   When a term *t* has been completed it is copied to, added to, or subtracted from the expression *e*.

> **define** *expr_add_sub*(#) ≡ *add_or_sub*(#, *r* = *expr_sub*)
> **define** *expr_a*(#) ≡ *expr_add_sub*(#, *max_dimen*)

⟨ Evaluate the current expression 1603 ⟩ ≡
  begin $s ← expr\_none$;
  if $r = expr\_none$ **then** $e ← t$
  else if $l = int\_val$ **then** $e ← expr\_add\_sub(e, t, infinity)$
    else if $l = dimen\_val$ **then** $e ← expr\_a(e, t)$
      else ⟨ Compute the sum or difference of two glue specs 1605 ⟩;
  $r ← o$;
  end
This code is used in section 1594.

1604. The function $add\_or\_sub(x, y, max\_answer, negative)$ computes the sum (for $negative = false$) or difference (for $negative = true$) of x and y, provided the absolute value of the result does not exceed max_answer.

⟨ Declare subprocedures for $scan\_expr$ 1604 ⟩ ≡

function $add\_or\_sub(x, y, max\_answer : integer; negative : boolean): integer;$
 var a: $integer$; { the answer }
 begin if $negative$ **then** $negate(y)$;
 if $x \geq 0$ **then**
  if $y \leq max\_answer - x$ **then** $a \leftarrow x + y$ **else** $num\_error(a)$
  else if $y \geq -max\_answer - x$ **then** $a \leftarrow x + y$ **else** $num\_error(a)$;
 $add\_or\_sub \leftarrow a$;
 end;

See also sections 1608 and 1610.

This code is used in section 1593.

1605. We know that $stretch\_order(e) > normal$ implies $stretch(e) \neq 0$ and $shrink\_order(e) > normal$ implies $shrink(e) \neq 0$.

⟨ Compute the sum or difference of two glue specs 1605 ⟩ ≡

 begin $width(e) \leftarrow expr\_a(width(e), width(t))$;
 if $stretch\_order(e) = stretch\_order(t)$ **then** $stretch(e) \leftarrow expr\_a(stretch(e), stretch(t))$
 else if $(stretch\_order(e) < stretch\_order(t)) \wedge (stretch(t) \neq 0)$ **then**
  begin $stretch(e) \leftarrow stretch(t)$; $stretch\_order(e) \leftarrow stretch\_order(t)$;
  end;
 if $shrink\_order(e) = shrink\_order(t)$ **then** $shrink(e) \leftarrow expr\_a(shrink(e), shrink(t))$
 else if $(shrink\_order(e) < shrink\_order(t)) \wedge (shrink(t) \neq 0)$ **then**
  begin $shrink(e) \leftarrow shrink(t)$; $shrink\_order(e) \leftarrow shrink\_order(t)$;
  end;
 $delete\_glue\_ref(t)$; $normalize\_glue(e)$;
 end

This code is used in section 1603.

1606. If a multiplication is followed by a division, the two operations are combined into a 'scaling' operation. Otherwise the term t is multiplied by the factor f.

 define $expr\_m(\texttt{\#}) \equiv \texttt{\#} \leftarrow nx\_plus\_y(\texttt{\#}, f, 0)$

⟨ Cases for evaluation of the current term 1602 ⟩ +≡

$expr\_mult$: **if** $o = expr\_div$ **then**
 begin $n \leftarrow f$; $o \leftarrow expr\_scale$;
 end
 else if $l = int\_val$ **then** $t \leftarrow mult\_integers(t, f)$
  else if $l = dimen\_val$ **then** $expr\_m(t)$
   else begin $expr\_m(width(t))$; $expr\_m(stretch(t))$; $expr\_m(shrink(t))$;
    end;

1607. Here we divide the term t by the factor f.

 define $expr\_d(\texttt{\#}) \equiv \texttt{\#} \leftarrow quotient(\texttt{\#}, f)$

⟨ Cases for evaluation of the current term 1602 ⟩ +≡

$expr\_div$: **if** $l < glue\_val$ **then** $expr\_d(t)$
 else begin $expr\_d(width(t))$; $expr\_d(stretch(t))$; $expr\_d(shrink(t))$;
  end;

1608.   The function $quotient(n, d)$ computes the rounded quotient $q = \lfloor n/d + \frac{1}{2} \rfloor$, when n and d are positive.

$\langle$ Declare subprocedures for $scan\_expr$ 1604 $\rangle$ $+\equiv$
function $quotient(n, d : integer): integer;$
  var $negative: boolean;$ { should the answer be negated? }
    $a: integer;$ { the answer }
  begin if $d = 0$ **then** $num\_error(a)$
  else begin if $d > 0$ **then** $negative \leftarrow false$
    else begin $negate(d);$ $negative \leftarrow true;$
      end;
    if $n < 0$ **then**
      begin $negate(n);$ $negative \leftarrow \neg negative;$
      end;
    $a \leftarrow n$ **div** $d;$ $n \leftarrow n - a * d;$ $d \leftarrow n - d;$ { avoid certain compiler optimizations! }
    if $d + n \geq 0$ **then** $incr(a);$
    if $negative$ **then** $negate(a);$
    end;
  $quotient \leftarrow a;$
  end;

1609.   Here the term t is multiplied by the quotient n/f.

  define $expr\_s(\#) \equiv \# \leftarrow fract(\#, n, f, max\_dimen)$

$\langle$ Cases for evaluation of the current term 1602 $\rangle$ $+\equiv$
$expr\_scale:$ **if** $l = int\_val$ **then** $t \leftarrow fract(t, n, f, infinity)$
  else if $l = dimen\_val$ **then** $expr\_s(t)$
    else begin $expr\_s(width(t));$ $expr\_s(stretch(t));$ $expr\_s(shrink(t));$
      end;

1610.   Finally, the function $fract(x, n, d, max\_answer)$ computes the integer $q = \lfloor xn/d + \frac{1}{2} \rfloor$, when x, n, and d are positive and the result does not exceed max_answer. We can't use floating point arithmetic since the routine must produce identical results in all cases; and it would be too dangerous to multiply by n and then divide by d, in separate operations, since overflow might well occur. Hence this subroutine simulates double precision arithmetic, somewhat analogous to METAFONT's $make\_fraction$ and $take\_fraction$ routines.

define $too\_big = 88$ { go here when the result is too big }

$done:$ $fract \leftarrow a;$
  end;

1611.   The loop here preserves the following invariant relations between f, x, n, and r: (i) $f + \lfloor(xn + (r + d))/d\rfloor = \lfloor x_0 n_0/d + \frac{1}{2}\rfloor$; (ii) $-d \le r < 0 < n \le x < d$, where x_0, n_0 are the original values of x and n.
   Notice that the computation specifies $(x - d) + x$ instead of $(x + x) - d$, because the latter could overflow.

$\langle$ Compute $f = \lfloor xn/d + \frac{1}{2}\rfloor$ 1611 $\rangle \equiv$
   $f \leftarrow 0$; $r \leftarrow (d \textbf{ div } 2) - d$; $h \leftarrow -r$;
   loop begin if $odd(n)$ **then**

1620. ε-TEX (in extended mode) supports 32768 (i.e., 2^{15}) count, dimen, skip, muskip, box, and token registers. As in TEX the first 256 registers of each kind are realized as arrays in the table of equivalents; the additional registers are realized as tree structures built from variable-size nodes with individual registers existing only when needed. Default values are used for nonexistent registers: zero for count and dimen values, *zero_glue* for glue (skip and muskip) values, void for boxes, and *null* for token lists (and current marks discussed below).

Similarly there are 32768 mark classes; the command \marks*n* creates a mark node for a given mark class $0 \leq n \leq 32767$ (where \marks0 is synonymous to \mark). The page builder (actually the *fire_up* routine) and the *vsplit* routine maintain the current values of *top_mark*, *first_mark*, *bot_mark*, *split_first_mark*, and *split_bot_mark* for each mark class. They are accessed as \topmarks*n* etc., and \topmarks0 is again synonymous to \topmark. As in TEX the five current marks for mark class zero are realized as *cur_mark* array. The additional current marks are again realized as tree structure with individual mark classes existing only when needed.

1625. ⟨Global variables 13⟩ +≡
max_reg_num: $halfword$; { largest allowed register number }
$max\_reg\_help\_line$: str_number; { first line of help message }

1626.   There are eight almost identical doubly linked trees, one for the sparse array of the up to 32512 additional registers of each kind, one for inter-character token lists at specified class transitions, and one for the sparse array of the up to 32767 additional mark classes. The root of each such tree, if it exists, is an index node containing 64 pointers to subtrees for 64^4 consecutive array elements. Similar index nodes are the starting points for all nonempty subtrees for 64^3, 64^2, and 64 consecutive array elements. These four levels of index nodes are followed by a fifth level with nodes for the individual array elements.

Each index node is 33 words long. The pointers to the 64 possible subtrees or nodes are kept in the *info* and *link* fields of the last 32 words. (It would be both elegant and efficient to declare them as array, unfortunately Pascal doesn't allow this.)

The fields in the first word of each index node and in the nodes for the array elements are closely related. The *link* field points to the next lower index node and the *sa_index* field contains four bits (one hexadecimal digit) of the register number or mark class. For the lowest index node the *link* field is *null* and the *sa_index* field indicates the type of quantity (*int_val*, *dimen_val*, *glue_val*, *mu_val*, *box_val*, *tok_val*, *inter_char_val* or *mark_val*). The *sa_used* field in the index nodes counts how many of the 64 pointers are non-null.

The *sa_index* field in the nodes for array elements contains the six bits plus 64 times the type. Therefore such a node represents a count or dimen register if and only if $sa\_index < dimen\_val\_limit$; it represents a skip or muskip register if and only if $dimen\_val\_limit \leq sa\_index < mu\_val\_limit$; it represents a box register if and only if $mu\_val\_limit \leq sa\_index < box\_val\_limit$; it represents a token list register if and only if $box\_val\_limit \leq sa\_index < tok\_val\_limit$; finally it represents a mark class if and only if $tok\_val\_limit \leq sa\_index$.

The *new_index* procedure creates an index node (returned in *cur_ptr*) having given contents of the *sa_index* and *link* fields.

> **define** $box\_val \equiv 4$ { the additional box registers }
> **define** $mark\_val = 7$ { the additional mark classes }
>

1630.   Given a type t and a twenty-four-bit number n, the *find_sa_element* procedure returns (in *cur_ptr*) a pointer to the node for the corresponding array element, or *null* when no such element exists. The third parameter w is set *true* if the element must exist, e.g., because it is about to be modified. The procedure has two main branches: one follows the existing tree structure, the other (only used when w is *true*) creates the missing nodes.

We use macros to extract the six-bit pieces from a twenty-four-bit register number or mark class and to fetch or store one of the 64 pointers from an index node. (Note that the *hex_dig* macros are mis-named since the conversion from 4-bit to 6-bit fields for X$_{\exists}$TEX!)

exit: **end**;

1631.   The array elements for registers are subject to grouping and have an sa_lev field (quite analogous to eq_level) instead of sa_used. Since saved values as well as shorthand definitions (created by e.g., \countdef) refer to the location of the respective array element, we need a reference count that is kept in the sa_ref field. An array element can be deleted (together with all references to it) when its sa_ref value is *null* and its value is the default value.

Skip, muskip, box, and token registers use two word nodes, their values are stored in the sa_ptr field. Count and dimen registers use three word nodes, their values are stored in the sa_int resp. sa_dim field in the third word; the sa_ptr field is used under the name sa_num to store the register number. Mark classes use four word nodes. The last three words contain the five types of current marks

define $sa\_lev \equiv sa\_used$ { grouping level for the current value }
define $pointer\_node\_size = 2$ { size of an element with a pointer value }
define $sa\_type(\#) \equiv (sa\_index(\#)$ **div** $64)$ { type part of combined type/index }
define $sa\_ref(\#) \equiv info(\# + 1)$ { reference count of a sparse array element }
define $sa\_ptr(\#) \equiv link(\# + 1)$ { a pointer value }

define $word\_node\_size = 3$ { size of an element with a word value }
define $sa\_num \equiv sa\_ptr$ { the register number }
define $sa\_int(\#) \equiv mem[\# + 2].int$ { an integer }
define $sa\_dim(\#) \equiv mem[\# + 2].sc$ { a dimension (a somewhat esotheric distinction) }

define $mark\_class\_node\_size = 4$ { size of an element for a mark class }

define $fetch\_box(\#) \equiv$ { fetch $box(cur\_val)$ }
          if $cur\_val < 256$ **then** $\# \leftarrow box(cur\_val)$
          else begin $find\_sa\_element(box\_val, cur\_val, false)$;
            if $cur\_ptr = null$ **then** $\# \leftarrow null$ **else** $\# \leftarrow sa\_ptr(cur\_ptr)$;
            end

⟨ Create a new array element of type t with index i 1631 ⟩ ≡
  if $t = mark\_val$ **then**   { a mark class }
    begin $cur\_ptr \leftarrow get\_node(mark\_class\_node\_size)$; $mem[cur\_ptr + 1] \leftarrow sa\_null$;
    $mem[cur\_ptr + 2] \leftarrow sa\_null$; $mem[cur\_ptr + 3] \leftarrow sa\_null$;
    end
  else begin if $t \leq dimen\_val$ **then**   { a count or dimen register }

        end
      else $sa\_ptr(cur\_ptr) \leftarrow null$;   { a box or token list register }
      end;
    $sa\_ref(cur\_ptr) \leftarrow null$;   { all registers have a reference count }
    end;
  $sa\_index(cur\_ptr) \leftarrow 64 * t + i$; $sa\_lev(cur\_ptr) \leftarrow level\_one$
This code is used in section 1630.

1632. The *delete_sa_ref* procedure is called when a pointer to an array element representing a register is being removed; this means that the reference count should be decreased by one. If the reduced reference count is *null* and the register has been (globally) assigned its default value the array element should disappear, possibly together with some index nodes. This procedure will never be used for mark class nodes.

> **define** *add_sa_ref* (#) ≡ *incr* (*sa_ref* (#))   { increase reference count }

  tats

1635.   Here we compute the pointer to the current mark of type *t* and mark class *cur_val*.

⟨ Compute the mark pointer for mark type *t* and class *cur_val* 1635 ⟩ ≡
  begin *find_sa_element*(*mark_val*, *cur_val*, *false*);
  if *cur_ptr* ≠ *null* **then**
    if *odd*(*t*) **then** *cur_ptr* ← *link*(*cur_ptr* + (*t* **div** 2) + 1)
    else *cur_ptr* ← *info*(*cur_ptr* + (*t* **div** 2) + 1);
  end

This code is used in section 420.

1636.   The current marks for all mark classes are maintained by the *vsplit* and *fire_up* routines and are finally destroyed (for `INITEX` only) by the *final_cleanup* routine. Apart from updating the current marks when mark nodes are encountered, these routines perform certain actions on all existing mark classes. The recursive *do_marks* procedure walks through the whole tree or a subtree of existing mark class nodes and preforms certain actions indicted by its first parameter *a*, the action code. The second parameter *l* indicates the level of recursion (at most four); the third parameter points to a nonempty tree or subtree. The result is *true* if the complete tree or subtree has been deleted.

> **define** *vsplit_init* ≡ 0   { action code for *vsplit* initialization }

⟨ Declare the function called *do_marks* 1636 ⟩ ≡
function *do_marks*(*a*, *l* : *small_number*; *q* : *pointer*): *boolean*;
  var *i*: *small_number*;   { a four bit index }
  begin if *l* < 4 **then**   { *q* is an index node }
    begin for *i* ← 0 **to** 15 **do**
      begin *get_sa_ptr*;
      if *cur_ptr* ≠ *null* **then**
        if *do_marks*(*a*, *l* + 1, *cur_ptr*) **then** *delete_sa_ptr*;
      end;
    if *sa_used*(*q*) = 0 **then**
      begin *free_node*(*q*, *index_node_size*); *q* ← *null*;
      end;
    end
  else   { *q* is the node for a mark class }
  begin case *a* **of**
    ⟨ Cases for *do_marks* 1637 ⟩
  end;   { there are no other cases }
  if *sa_bot_mark*(*q*) = *null* **then**
    if *sa_split_bot_mark*(*q*) = *null* **then**
      begin *free_node*(*q*, *mark_class_node_size*); *q* ← *null*;
      end;
  end; *do_marks* ← (*q* = *null*);
  end;

This code is used in section 1031.

1637.   At the start of the *vsplit* routine the existing *split_fist_mark* and *split_bot_mark* are discarded.

⟨ Cases for *do_marks* 1637 ⟩ ≡
vsplit_init: **if** *sa_split_first_mark*(*q*) ≠ *null* **then**
    begin *delete_token_ref*(*sa_split_first_mark*(*q*)); *sa_split_first_mark*(*q*) ← *null*;
    delete_token_ref(*sa_split_bot_mark*(*q*)); *sa_split_bot_mark*(*q*) ← *null*;
    end;

See also sections 1639, 1640, and 1642.

This code is used in section 1636.

1638. We use again the fact that *split_first_mark* = *null* if and only if *split_bot_mark* = *null*.

⟨ Update the current marks for *vsplit* 1638 ⟩ ≡
  begin *find_sa_element*(*mark_val*, *mark_class*(*p*), *true*);
  if *sa_split_first_mark*(*cur_ptr*) = *null* **then**
    begin *sa_split_first_mark*(*cur_ptr*) ← *mark_ptr*(*p*); *add_token_ref*(*mark_ptr*(*p*));
    end
  else *delete_token_ref*(*sa_split_bot_mark*(*cur_ptr*));
  sa_split_bot_mark(*cur_ptr*) ← *mark_ptr*(*p*); *add_token_ref*(*mark_ptr*(*p*));
  end

This code is used in section 1033.

1639. At the start of the *fire_up* routine the old *top_mark* and *first_mark* are discarded, whereas the old *bot_mark* becomes the new *top_mark*. An empty new *top_mark* token list is, however, discarded as well in order that mark class nodes can eventually be released. We use again the fact that *bot_mark* ≠ *null* implies *first_mark* ≠ *null*; it also knows that *bot_mark* = *null* implies *top_mark* = *first_mark* = *null*.

⟨ Cases for *do_marks* 1637 ⟩ +≡
fire_up_init: **if** *sa_bot_mark*(*q*) ≠ *null* **then**
    begin if *sa_top_mark*(*q*) ≠ *null* **then** *delete_token_ref*(*sa_top_mark*(*q*));
    delete_token_ref(*sa_first_mark*(*q*)); *sa_first_mark*(*q*) ← *null*;
    if *link*(*sa_bot_mark*(*q*)) = *null* **then**   { an empty token list }
      begin *delete_token_ref*(*sa_bot_mark*(*q*)); *sa_bot_mark*(*q*) ← *null*;
      end
    else *add_token_ref*(*sa_bot_mark*(*q*));
    sa_top_mark(*q*) ← *sa_bot_mark*(*q*);
    end;

1640. ⟨ Cases for *do_marks* 1637 ⟩ +≡
fire_up_done: **if** (*sa_top_mark*(*q*) ≠ *null*) ∧ (*sa_first_mark*(*q*) = *null*) **then**
    begin *sa_first_mark*(*q*) ← *sa_top_mark*(*q*); *add_token_ref*(*sa_top_mark*(*q*));
    end;

1641. ⟨ Update the current marks for *fire_up* 1641 ⟩ ≡
  begin *find_sa_element*(*mark_val*, *mark_class*(*p*), *true*);
  if *sa_first_mark*(*cur_ptr*) = *null* **then**
    begin *sa_first_mark*(*cur_ptr*) ← *mark_ptr*(*p*); *add_token_ref*(*mark_ptr*(*p*));
    end;
  if *sa_bot_mark*(*cur_ptr*) ≠ *null* **then** *delete_token_ref*(*sa_bot_mark*(*cur_ptr*));
  sa_bot_mark(*cur_ptr*) ← *mark_ptr*(*p*); *add_token_ref*(*mark_ptr*(*p*));
  end

This code is used in section 1068.

1642. Here we use the fact that the five current mark pointers in a mark class node occupy the same locations as the the first five pointers of an index node. For systems using a run-time switch to distinguish between VIRTEX and INITEX, the codewords 'init ... tini' surrounding the following piece of code should be removed.

⟨ Cases for *do_marks* 1637 ⟩ +≡
  init *destroy_marks*: **for** $i \leftarrow top\_mark\_code$ **to** *split_bot_mark_code* **do**
    begin *get_sa_ptr*;
    if $cur\_ptr \neq null$ **then**
      begin *delete_token_ref*(*cur_ptr*); *put_sa_ptr*(*null*);
      end;
    end;
  tini

1643. The command code *register* is used for '\count', '\dimen', etc., as well as for references to sparse array elements defined by '\countdef', etc.

⟨ Cases of *register* for *print_cmd_chr* 1643 ⟩ ≡
  begin if $(chr\_code < mem\_bot) \vee (chr\_code > lo\_mem\_stat\_max)$ **then** $cmd \leftarrow sa\_type(chr\_code)$
  else begin $cmd \leftarrow chr\_code - mem\_bot$; $chr\_code \leftarrow null$;
    end;
  if $cmd = int\_val$ **then** *print_esc*("count")
  else if $cmd = dimen\_val$ **then** *print_esc*("dimen")
    else if $cmd = glue\_val$ **then** *print_esc*("skip")
      else *print_esc*("muskip");
  if $chr\_code \neq null$ **then** *print_sa_num*(*chr_code*);
  end

This code is used in section 446.

1644. Similarly the command code *toks_register* is used for '\toks' as well as for references to sparse array elements defined by '\toksdef'.

⟨ Cases of *toks_register* for *print_cmd_chr* 1644 ⟩ ≡
  begin *print_esc*("toks");
  if $chr\_code \neq mem\_bot$ **then** *print_sa_num*(*chr_code*);
  end

This code is used in section 296.

1645. When a shorthand definition for an element of one of the sparse arrays is destroyed, we must reduce the reference count.

⟨ Cases for *eq_destroy* 1645 ⟩ ≡
toks_register, *register*: **if** $(equiv\_field(w) < mem\_bot) \vee (equiv\_field(w) > lo\_mem\_stat\_max)$ **then**
    delete_sa_ref(*equiv_field*(*w*));

This code is used in section 305.

1646. The task to maintain (change, save, and restore) register values is essentially the same when the register is realized as sparse array element or entry in *eqtb*. The global variable *sa_chain* is the head of a linked list of entries saved at the topmost level *sa_level*; the lists for lowel levels are kept in special save stack entries.

⟨ Global variables 13 ⟩ +≡
sa_chain: *pointer*;   { chain of saved sparse array entries }
sa_level: *quarterword*;   { group level for *sa_chain* }

1647. ⟨Set initial values of key variables 23⟩ +≡
  $sa\_chain \leftarrow null$; $sa\_level \leftarrow level\_zero$;

1648. The individual saved items are kept in pointer or word nodes similar to those used for the array elements: a word node with value zero is, however, saved as pointer node with the otherwise impossible sa_index value tok_val_limit.

  define $sa\_loc \equiv sa\_ref$ { location of saved item }

⟨Declare ε-T$_E$X procedures for tracing and input 314⟩ +≡
procedure $sa\_save(p : pointer)$;   { saves value of p }
  var q: $pointer$;   { the new save node }
    i: $quarterword$;   { index field of node }
  begin if $cur\_level \neq sa\_level$ **then**
    begin $check\_full\_save\_stack$; $save\_type(save\_ptr) \leftarrow restore\_sa$; $save\_level(save\_ptr) \leftarrow sa\_level$;
    $save\_index(save\_ptr) \leftarrow sa\_chain$; $incr(save\_ptr)$; $sa\_chain \leftarrow null$; $sa\_level \leftarrow cur\_level$;
    end;
  $i \leftarrow sa\_index(p)$;
  if $i < dimen\_val\_limit$ **then**
    begin if $sa\_int(p) = 0$ **then**
      begin $q \leftarrow get\_node(pointer\_node\_size)$; $i \leftarrow tok\_val\_limit$;
      end
    else begin $q \leftarrow get\_node(word\_node\_size)$; $sa\_int(q) \leftarrow sa\_int(p)$;
      end;
    $sa\_ptr(q) \leftarrow null$;
    end
  else begin $q \leftarrow get\_node(pointer\_node\_size)$; $sa\_ptr(q) \leftarrow sa\_ptr(p)$;
    end;
  $sa\_loc(q) \leftarrow p$; $sa\_index(q) \leftarrow i$; $sa\_lev(q) \leftarrow sa\_lev(p)$; $link(q) \leftarrow sa\_chain$; $sa\_chain \leftarrow q$; $add\_sa\_ref(p)$;
  end;

1649. ⟨Declare ε-T$_E$X procedures for tracing and input 314⟩ +≡
procedure $sa\_destroy(p : pointer)$;   { destroy value of p }
  begin if $sa\_index(p) < mu\_val\_limit$ **then** $delete\_glue\_ref(sa\_ptr(p))$
  else if $sa\_ptr(p) \neq null$ **then**
    if $sa\_index(p) < box\_val\_limit$ **then** $flush\_node\_list(sa\_ptr(p))$
    else $delete\_token\_ref(sa\_ptr(p))$;
  end;

1650. The procedure *sa_def* assigns a new value to sparse array elements, and saves the former value if appropriate. This procedure is used only for skip, muskip, box, and token list registers. The counterpart of *sa_def* for count and dimen registers is called *sa_w_def*.

define *sa_define*(#) ≡
       if *e* **then**
         if *global* **then** *gsa_def*(#) **else** *sa_def*(#)
       else *define*
define *sa_def_box* ≡   { assign *cur_box* to *box*(*cur_val*) }
      begin *find_sa_element*(*box_val*, *cur_val*, *true*);
      if *global* **then** *gsa_def*(*cur_ptr*, *cur_box*) **else** *sa_def*(*cur_ptr*, *cur_box*);
      end
define *sa_word_define*(#) ≡
       if *e* **then**
         if *global* **then** *gsa_w_def*(#) **else** *sa_w_def*(#)
       else *word_define*(#)

⟨ Declare ε-TEX procedures for tracing and input 314 ⟩ +≡
procedure *sa_def*(*p* : *pointer*; *e* : *halfword*);   { new data for sparse array elements }
  begin *add_sa_ref*(*p*);
  if *sa_ptr*(*p*) = *e* **then**
    begin stat if *tracing_assigns* > 0 **then** *show_sa*(*p*, "reassigning");
    tats
    sa_destroy(*p*);
    end
  else begin stat if *tracing_assigns* > 0 **then** *show_sa*(*p*, "changing");
    tats
    if *sa_lev*(*p*) = *cur_level* **then** *sa_destroy*(*p*) **else** *sa_save*(*p*);
    sa_lev(*p*) ← *cur_level*; *sa_ptr*(*p*) ← *e*;
    stat if *tracing_assigns* > 0 **then** *show_sa*(*p*, "into");
    tats
    end;
  delete_sa_ref(*p*);
  end;

procedure *sa_w_def*(*p* : *pointer*; *w* : *integer*);
  begin *add_sa_ref*(*p*);

    stat if *tracing_assigns* > 0 **then** *show_sa*(*p*, "into");
    tats
    end;
  delete_sa_ref(*p*);
  end;

1651. The *sa_def* and *sa_w_def* routines take care of local definitions. Global definitions are done in almost the same way, but there is no need to save old values, and the new value is associated with *level_one*.

⟨Declare ε-TEX procedures for tracing and input 314⟩ +≡
procedure *gsa_def* (*p* : *pointer*; *e* : *halfword*);   { global *sa_def* }
  begin *add_sa_ref* (*p*);
  stat if *tracing_assigns* > 0 **then** *show_sa*(*p*, "globally␣changing");
  tats
  sa_destroy(*p*); *sa_lev*(*p*) ← *level_one*; *sa_ptr*(*p*) ← *e*;
  stat if *tracing_assigns* > 0 **then** *show_sa*(*p*, "into");
  tats
  delete_sa_ref (*p*);
  end;

procedure *gsa_w_def* (*p* : *pointer*; *w* : *integer*);   { global *sa_w_def* }
  begin *add_sa_ref* (*p*);
  stat if *tracing_assigns* > 0 **then** *show_sa*(*p*, "globally␣changing");
  tats
  sa_lev(*p*) ← *level_one*; *sa_int*(*p*) ← *w*;
  stat if *tracing_assigns* > 0 **then** *show_sa*(*p*, "into");
  tats
  delete_sa_ref (*p*);
  end;

1652. The *sa_restore* procedure restores the sparse array entries pointed at by *sa_chain*

⟨Declare ε-TEX procedures for tracing and input 314⟩ +≡
procedure *sa_restore*;
  var *p*: *pointer*;   { sparse array element }
  begin repeat *p* ← *sa_loc*(*sa_chain*);
    if *sa_lev*(*p*) = *level_one* **then**
      begin if *sa_index*(*p*) ≥ *dimen_val_limit* **then** *sa_destroy*(*sa_chain*);
      stat if *tracing_restores* > 0 **then** *show_sa*(*p*, "retaining");
      tats
      end
    else begin if *sa_index*(*p*) < *dimen_val_limit* **then**
        if *sa_index*(*sa_chain*) < *dimen_val_limit* **then** *sa_int*(*p*) ← *sa_int*(*sa_chain*)
        else *sa_int*(*p*) ← 0
      else begin *sa_destroy*(*p*); *sa_ptr*(*p*) ← *sa_ptr*(*sa_chain*);
        end;
      sa_lev(*p*) ← *sa_lev*(*sa_chain*);
      stat if *tracing_restores* > 0 **then** *show_sa*(*p*, "restoring");
      tats
      end;
    delete_sa_ref (*p*); *p* ← *sa_chain*; *sa_chain* ← *link*(*p*);
    if *sa_index*(*p*) < *dimen_val_limit* **then** *free_node*(*p*, *word_node_size*)
    else *free_node*(*p*, *pointer_node_size*);
  until *sa_chain* = *null*;
  end;

1653.   When the value of *last_line_fit* is positive, the last line of a (partial) paragraph is treated in a special way and we need additional fields in the active nodes.

    define *active_node_size_extended* = 5   { number of words in extended active nodes }
    define *active_short*(#) ≡ *mem*[# + 3].*sc*   { *shortfall* of this line }
    define *active_glue*(#) ≡ *mem*[# + 4].*sc*   { corresponding glue stretch or shrink }

⟨ Global variables 13 ⟩ +≡
last_line_fill: *pointer*;   { the *par_fill_skip* glue node of the new paragraph }
do_last_line_fit: *boolean*;   { special algorithm for last line of paragraph? }
active_node_size: *small_number*;   { number of words in active nodes }
fill_width: **array** [0 . . 2] **of** *scaled*;   { infinite stretch components of *par_fill_skip* }
best_pl_short: **array** [*very_loose_fit* . . *tight_fit*] **of** *scaled*;   { *shortfall* corresponding to *minimal_demerits* }
best_pl_glue: **array** [*very_loose_fit* . . *tight_fit*] **of** *scaled*;   { corresponding glue stretch or shrink }

1654.   The new algorithm for the last line requires that the stretchability of *par_fill_skip* is infinite and the stretchability of *left_skip* plus *right_skip* is finite.

⟨ Check for special treatment of last line of paragraph 1654 ⟩ ≡
    do_last_line_fit ← *false*; *active_node_size* ← *active_node_size_normal*;   { just in case }
    if *last_line_fit* > 0 **then**
      begin *q* ← *glue_ptr*(*last_line_fill*);
      if (*stretch*(*q*) > 0) ∧ (*stretch_order*(*q*) > *normal*) **then**
        if (*background*[3] = 0) ∧ (*background*[4] = 0) ∧ (*background*[5] = 0) **then**
          begin *do_last_line_fit* ← *true*; *active_node_size* ← *active_node_size_extended*; *fill_width*[0] ← 0;
          fill_width[1] ← 0; *fill_width*[2] ← 0; *fill_width*[*stretch_order*(*q*) − 1] ← *stretch*(*q*);
          end;
      end
This code is used in section 875.

1655.   ⟨ Other local variables for *try_break* 878 ⟩ +≡
g: *scaled*;   { glue stretch or shrink of test line, adjustment for last line }

1656.   Here we initialize the additional fields of the first active node representing the beginning of the paragraph.

⟨ Initialize additional fields of the first active node 1656 ⟩ ≡
    begin *active_short*(*q*) ← 0; *active_glue*(*q*) ← 0;
    end
This code is used in section 912.

1657.   Here we compute the adjustment g and badness b for a line from r to the end of the paragraph. When any of the criteria for adjustment is violated we fall through to the normal algorithm.

The last line must be too short, and have infinite stretch entirely due to *par_fill_skip*.

⟨ Perform computations for last line and **goto** *found* 1657 ⟩ ≡
    begin if $(active\_short(r) = 0) \vee (active\_glue(r) \leq 0)$ **then goto** *not_found*;
            { previous line was neither stretched nor shrunk, or was infinitely bad }
    if $(cur\_active\_width[3] \neq fill\_width[0]) \vee (cur\_active\_width[4] \neq fill\_width[1]) \vee$
            $(cur\_active\_width[5] \neq fill\_width[2])$ **then goto** *not_found*;
            { infinite stretch of this line not entirely due to *par_fill_skip* }
    if $active\_short(r) > 0$ **then** $g \leftarrow cur\_active\_width[2]$
    else $g \leftarrow cur\_active\_width[6]$;
    if $g \leq 0$ **then goto** *not_found*;   { no finite stretch resp. no shrink }
    $arith\_error \leftarrow false$; $g \leftarrow fract(g, active\_short(r), active\_glue(r), max\_dimen)$;
    if $last\_line\_fit < 1000$ **then** $g \leftarrow fract(g, last\_line\_fit, 1000, max\_dimen)$;
    if *arith_error* **then**
        if $active\_short(r) > 0$ **then** $g \leftarrow max\_dimen$ **else** $g \leftarrow -max\_dimen$;
    if $g > 0$ **then** ⟨ Set the value of b to the badness of the last line for stretching, compute the corresponding
            fit_class, and **goto** *found* 1658 ⟩
    else if $g < 0$ **then** ⟨ Set the value of b to the badness of the last line for shrinking, compute the
            corresponding *fit_class*, and **goto** *found* 1659 ⟩;
not_found: **end**

This code is used in section 900.

1658.   These badness computations are rather similar to those of the standard algorithm, with the adjustment amount g replacing the *shortfall*.

⟨ Set the value of b to the badness of the last line for stretching, compute the corresponding *fit_class*, and
        goto *found* 1658 ⟩ ≡
    begin if $g > shortfall$ **then** $g \leftarrow shortfall$;
    if $g > 7230584$ **then**
        if $cur\_active\_width[2] < 1663497$ **then**
            begin $b \leftarrow inf\_bad$; $fit\_class \leftarrow very\_loose\_fit$; **goto** *found*;
            end;
    $b \leftarrow badness(g, cur\_active\_width[2])$;
    if $b > 12$ **then**
        if $b > 99$ **then** $fit\_class \leftarrow very\_loose\_fit$
        else $fit\_class \leftarrow loose\_fit$
    else $fit\_class \leftarrow decent\_fit$;
    goto *found*;
    end

This code is used in section 1657.

1659.   ⟨ Set the value of b to the badness of the last line for shrinking, compute the corresponding *fit_class*,
        and **goto** *found* 1659 ⟩ ≡
    begin if $-g > cur\_active\_width[6]$ **then** $g \leftarrow -cur\_active\_width[6]$;
    $b \leftarrow badness(-g, cur\_active\_width[6])$;
    if $b > 12$ **then** $fit\_class \leftarrow tight\_fit$ **else** $fit\_class \leftarrow decent\_fit$;
    goto *found*;
    end

This code is used in section 1657.

1660.   Vanishing values of *shortfall* and *g* indicate that the last line is not adjusted.

⟨ Adjust the additional data for last line 1660 ⟩ ≡
  begin if *cur_p* = *null* **then** *shortfall* ← 0;
  if *shortfall* > 0 **then** *g* ← *cur_active_width*[2]
  else if *shortfall* < 0 **then** *g* ← *cur_active_width*[6]
    else *g* ← 0;
  end

This code is used in section 899.

1661.   For each feasible break we record the shortfall and glue stretch or shrink (or adjustment).

⟨ Store additional data for this feasible break 1661 ⟩ ≡
  begin *best_pl_short*[*fit_class*] ← *shortfall*; *best_pl_glue*[*fit_class*] ← *g*;
  end

This code is used in section 903.

1662.   Here we save these data in the active node representing a potential line break.

⟨ Store additional data in the new active node 1662 ⟩ ≡
  begin *active_short*(*q*) ← *best_pl_short*[*fit_class*]; *active_glue*(*q*) ← *best_pl_glue*[*fit_class*];
  end

This code is used in section 893.

1663.   ⟨ Print additional data in the new active node 1663 ⟩ ≡
  begin *print*("␣s="); *print_scaled*(*active_short*(*q*));
  if *cur_p* = *null* **then** *print*("␣a=") **else** *print*("␣g=");
  print_scaled(*active_glue*(*q*));
  end

This code is used in section 894.

1664.   Here we either reset *do_last_line_fit* or adjust the *par_fill_skip* glue.

⟨ Adjust the final line of the paragraph 1664 ⟩ ≡
  if *active_short*(*best_bet*) = 0 **then** *do_last_line_fit* ← *false*
  else begin *q* ← *new_spec*(*glue_ptr*(*last_line_fill*)); *delete_glue_ref*(*glue_ptr*(*last_line_fill*));
    width(*q*) ← *width*(*q*) + *active_short*(*best_bet*) − *active_glue*(*best_bet*); *stretch*(*q*) ← 0;
    glue_ptr(*last_line_fill*) ← *q*;
    end

This code is used in section 911.

1665.   When reading \patterns while \savinghyphcodes is positive the current *lc_code* values are stored together with the hyphenation patterns for the current language. They will later be used instead of the *lc_code* values for hyphenation purposes.

   The *lc_code* values are stored in the linked trie analogous to patterns p_1 of length 1, with *hyph_root* = *trie_r*[0] replacing *trie_root* and *lc_code*(*p_1*) replacing the *trie_op* code. This allows to compress and pack them together with the patterns with minimal changes to the existing code.

   define *hyph_root* ≡ *trie_r*[0]   { root of the linked trie for *hyph_codes* }

⟨ Initialize table entries (done by INITEX only) 189 ⟩ +≡
  XeTeX_hyphenatable_length ← 63;   { for backward compatibility with standard TeX by default }

1666. ⟨Store hyphenation codes for current language 1666⟩ ≡
   begin $c \leftarrow cur\_lang$; $first\_child \leftarrow false$; $p \leftarrow 0$;
   repeat $q \leftarrow p$; $p \leftarrow trie\_r[q]$;
   until $(p = 0) \vee (c \leq so(trie\_c[p]))$;
   if $(p = 0) \vee (c < so(trie\_c[p]))$ **then**
      ⟨Insert a new trie node between q and p, and make p point to it 1018⟩;
   $q \leftarrow p$; { now node q represents cur_lang }
   ⟨Store all current lc_code values 1667⟩;
   end

This code is used in section 1014.

1667.   We store all nonzero lc_code values, overwriting any previously stored values (and possibly wasting a few trie nodes that were used previously and are not needed now). We always store at least one lc_code value such that $hyph\_index$ (defined below) will not be zero.

⟨Store all current lc_code values 1667⟩ ≡
   $p \leftarrow trie\_l[q]$; $first\_child \leftarrow true$;
   for $c \leftarrow 0$ **to** 255 **do**
      if $(lc\_code(c) > 0) \vee ((c = 255) \wedge first\_child)$ **then**
         begin if $p = 0$ **then** ⟨Insert a new trie node between q and p, and make p point to it 1018⟩
         else $trie\_c[p] \leftarrow si(c)$;
         $trie\_o[p] \leftarrow qi(lc\_code(c))$; $q \leftarrow p$; $p \leftarrow trie\_r[q]$; $first\_child \leftarrow false$;
         end;
   if $first\_child$ **then** $trie\_l[q] \leftarrow 0$ **else** $trie\_r[q] \leftarrow 0$

This code is used in section 1666.

1668.   We must avoid to "take" location 1, in order to distinguish between lc_code values and patterns.

⟨Pack all stored $hyph\_codes$ 1668⟩ ≡
   begin if $trie\_root = 0$ **then**
      for $p \leftarrow 0$ **to** 255 **do** $trie\_min[p] \leftarrow p + 2$;
   $first\_fit(hyph\_root)$; $trie\_pack(hyph\_root)$; $hyph\_start \leftarrow trie\_ref[hyph\_root]$;
   end

This code is used in section 1020.

1669.   The global variable $hyph\_index$ will point to the hyphenation codes for the current language.

   define $set\_hyph\_index \equiv$ { set $hyph\_index$ for current language }
         if $trie\_char(hyph\_start + cur\_lang) \neq qi(cur\_lang)$ **then** $hyph\_index \leftarrow 0$
               { no hyphenation codes for cur_lang }
         else $hyph\_index \leftarrow trie\_link(hyph\_start + cur\_lang)$
   define $set\_lc\_code(\#) \equiv$ { set $hc[0]$ to hyphenation or lc code for # }
         if $(hyph\_index = 0) \vee ((\#) > 255)$ **then** $hc[0] \leftarrow lc\_code(\#)$
         else if $trie\_char(hyph\_index + \#) \neq qi(\#)$ **then** $hc[0] \leftarrow 0$
            else $hc[0] \leftarrow qo(trie\_op(hyph\_index + \#))$
⟨Global variables 13⟩ +≡
$hyph\_start$: $trie\_pointer$; { root of the packed trie for $hyph\_codes$ }
$hyph\_index$: $trie\_pointer$; { pointer to hyphenation codes for cur_lang }

1670. When *saving_vdiscards* is positive then the glue, kern, and penalty nodes removed by the page builder or by \vsplit from the top of a vertical list are saved in special lists instead of being discarded.

define *tail_page_disc* ≡ *disc_ptr*[*copy_code*]   { last item removed by page builder }
define *page_disc* ≡ *disc_ptr*[*last_box_code*]   { first item removed by page builder }
define *split_disc* ≡ *disc_ptr*[*vsplit_code*]   { first item removed by \vsplit }

⟨Global variables 13⟩ +≡
disc_ptr: **array** [*copy_code* .. *vsplit_code*] **of** *pointer*;   { list pointers }

1671. ⟨Set initial values of key variables 23⟩ +≡
page_disc ← *null*; *split_disc* ← *null*;

1672. The \pagediscards and \splitdiscards commands share the command code *un_vbox* with \unvbox and \unvcopy, they are distinguished by their *chr_code* values *last_box_code* and *vsplit_code*. These *chr_code* values are larger than *box_code* and *copy_code*.

⟨Generate all ε-TEX primitives 1399⟩ +≡
primitive("pagediscards", *un_vbox*, *last_box_code*);
primitive("splitdiscards", *un_vbox*, *vsplit_code*);

1673. ⟨Cases of *un_vbox* for *print_cmd_chr* 1673⟩ ≡
else if *chr_code* = *last_box_code* **then** *print_esc*("pagediscards")
  else if *chr_code* = *vsplit_code* **then** *print_esc*("splitdiscards")
This code is used in section 1162.

1674. ⟨Handle saved items and **goto** *done* 1674⟩ ≡
  begin *link*(*tail*) ← *disc_ptr*[*cur_chr*]; *disc_ptr*[*cur_chr*] ← *null*; **goto** *done*;
  end
This code is used in section 1164.

1675. The \interlinepenalties, \clubpenalties, \widowpenalties, and \displaywidowpenalties commands allow to define arrays of penalty values to be used instead of the corresponding single values.

define *inter_line_penalties_ptr* ≡ *equiv*(*inter_line_penalties_loc*)
define *club_penalties_ptr* ≡ *equiv*(*club_penalties_loc*)
define *widow_penalties_ptr* ≡ *equiv*(*widow_penalties_loc*)
define *display_widow_penalties_ptr* ≡ *equiv*(*display_widow_penalties_loc*)

⟨Generate all ε-TEX primitives 1399⟩ +≡
primitive("interlinepenalties", *set_shape*, *inter_line_penalties_loc*);
primitive("clubpenalties", *set_shape*, *club_penalties_loc*);
primitive("widowpenalties", *set_shape*, *widow_penalties_loc*);
primitive("displaywidowpenalties", *set_shape*, *display_widow_penalties_loc*);

1676. ⟨Cases of *set_shape* for *print_cmd_chr* 1676⟩ ≡
inter_line_penalties_loc: *print_esc*("interlinepenalties");
club_penalties_loc: *print_esc*("clubpenalties");
widow_penalties_loc: *print_esc*("widowpenalties");
display_widow_penalties_loc: *print_esc*("displaywidowpenalties");
This code is used in section 296.

1677. ⟨Fetch a penalties array element 1677⟩ ≡
  begin *scan_int*;
  if (*equiv*(*m*) = *null*) ∨ (*cur_val* < 0) **then** *cur_val* ← 0
  else begin if *cur_val* > *penalty*(*equiv*(*m*)) **then** *cur_val* ← *penalty*(*equiv*(*m*));
    cur_val ← *penalty*(*equiv*(*m*) + *cur_val*);
    end;
  end

This code is used in section 457.

1678.   System-dependent changes.   This section should be replaced, if necessary, by any special modifications of the program that are necessary to make TEX work at a particular installation. It is usually best to design your change file so that all changes to previous sections preserve the section numbering; then everybody's version will be consistent with the published program. More extensive changes, which introduce new sections, can be inserted here; then only the index itself will get a new section number.

1679.   Index.   Here is where you can find all uses of each identifier in the program, with underlined entries pointing to where the identifier was defined. If the identifier is only one letter long, however, you get to see only the underlined entries. *All references are to section numbers instead of page numbers.*

   This index also lists error messages and other aspects of the program that you might want to look up some day. For example, the entry for "system dependencies" lists all sections that should receive special attention from people who are installing TEX in a new operating environment. A list of various things that can't happen appears under "this can't happen". Approximately 40 sections are listed under "inner loop"; these account for about 60% of TEX's running time, exclusive of input and output.

⟨ Accumulate the constant until *cur_tok* is not a suitable digit 479 ⟩   Used in section 478.

⟨ Add the width of node *s* to *act_width* 919 ⟩   Used in section 917.

⟨ Add the width of node *s* to *break_width* 890 ⟩   Used in section 888.

⟨ Add the width of node *s* to *disc_width* 918 ⟩   Used in section 917.

⟨ Adjust for the magnification ratio 492 ⟩   Used in section 488.

⟨ Adjust for the setting of \globaldefs 1268 ⟩   Used in section 1265.

⟨ Adjust *shift_up* and *shift_down* for the case of a fraction line 790 ⟩   Used in section 787.

⟨ Adjust *shift_up* and *shift_down* for the case of no fraction line 789 ⟩   Used in section 787.

⟨ Adjust the LR stack for the *hlist_out* routine; if necessary reverse an hlist segment and **goto** *reswitch* 1527 ⟩
      Used in section 1526.

⟨ Adjust the LR stack for the *hpack* routine 1521 ⟩   Used in section 691.

⟨ Adjust the LR stack for the *init_math* routine 1548 ⟩   Used in section 1547.

⟨ Adjust the LR stack for the *just_reverse* routine 1550 ⟩   Used in section 1549.

⟨ Adjust the LR stack for the *post_line_break* routine 1518 ⟩   Used in sections 927, 929, and 1517.

⟨ Adjust the additional data for last line 1660 ⟩   Used in section 899.

⟨ Adjust the final line of the paragraph 1664 ⟩   Used in section 911.

⟨ Advance *cur_p* to the node following the present string of characters 915 ⟩   Used in section 914.

⟨ Advance past a whatsit node in the *line_break* loop 1422 ⟩   Used in section 914.

⟨ Advance past a whatsit node in the pre-hyphenation loop 1423 ⟩   Used in section 949.

⟨ Advance *r*; **goto** *found* if the parameter delimiter has been fully matched, otherwise **goto** *continue* 428 ⟩
      Used in section 426.

⟨ Advance *q* past ignorable nodes 657 ⟩   Used in sections 656, 656, and 656.

⟨ Allocate entire node *p* and **goto** *found* 151 ⟩   Used in section 149.

⟨ Allocate from the top of node *p* and **goto** *found* 150 ⟩   Used in section 149.

⟨ Apologize for inability to do the operation now, unless \unskip follows non-glue 1160 ⟩   Used in section 1159.

⟨ Apologize for not loading the font, **goto** *done* 602 ⟩   Used in sections 601 and 744.

⟨ Append a ligature and/or kern to the translation; **goto** *continue* if the stack of inserted ligatures is
      nonempty 964 ⟩   Used in section 960.

⟨ Append a new leader node that uses *cur_box* 1132 ⟩   Used in section 1129.

⟨ Append a new letter or a hyphen level 1016 ⟩   Used in section 1015.

⟨ Append a new letter or hyphen 991 ⟩   Used in section 989.

⟨ Append a normal inter-word space to the current list, then **goto** *big_switch* 1095 ⟩   Used in section 1084.

⟨ Append a penalty node, if a nonzero penalty is appropriate 938 ⟩   Used in section 928.

⟨ Append an insertion to the current page and **goto** *contribute* 1062 ⟩   Used in section 1054.

⟨ Append any *new_hlist* entries for *q*, and any appropriate penalties 815 ⟩   Used in section 808.

⟨ Append box *cur_box* to the current list, shifted by *box_context* 1130 ⟩   Used in section 1129.

⟨ Append character *cur_chr* and the following characters (if any) to the current hlist in the current font;
      goto *reswitch* when a non-character has been fetched 1088 ⟩   Used in section 1084.

⟨ Append characters of *hu*[*j* . .] to *major_tail*, advancing *j* 971 ⟩   Used in section 970.

⟨ Append inter-element spacing based on *r_type* and *t* 814 ⟩   Used in section 808.

⟨ Append tabskip glue and an empty box to list *u*, and update *s* and *t* as the prototype nodes are passed 857 ⟩
      Used in section 856.

⟨ Append the accent with appropriate kerns, then set *p* ← *q* 1179 ⟩   Used in section 1177.

⟨ Append the current tabskip glue to the preamble list 826 ⟩   Used in section 825.

⟨ Append the display and perhaps also the equation number 1258 ⟩   Used in section 1253.

⟨ Append the glue or equation number following the display 1259 ⟩   Used in section 1253.

⟨ Append the glue or equation number preceding the display 1257 ⟩   Used in section 1253.

⟨ Append the new box to the current vertical list, followed by the list of special nodes taken out of the box
      by the packager 936 ⟩   Used in section 928.

⟨ Append the value *n* to list *p* 992 ⟩   Used in section 991.

⟨ Assign the values *depth_threshold* ← *show_box_depth* and *breadth_max* ← *show_box_breadth* 262 ⟩   Used in
      section 224.

⟨Assignments 1271, 1272, 1275, 1278, 1279, 1280, 1282, 1286, 1288, 1289, 1295, 1296, 1302, 1306, 1307, 1310, 1318⟩ Used in section 1265.

⟨Attach list p to the current list, and record its length; then finish up and **return** 1174⟩ Used in section 1173.

⟨Attach subscript OpenType math kerning 806⟩ Used in sections 801 and 803.

⟨Attach superscript OpenType math kerning 807⟩ Used in sections 802 and 803.

⟨Attach the limits to y and adjust $height(v)$, $depth(v)$ to account for their presence 795⟩ Used in section 794.

⟨Back up an outer control sequence so that it can be reread 367⟩ Used in section 366.

⟨Basic printing procedures 57, 58, 59, 63, 66, 67, 68, 69, 292, 293, 553, 741, 1415, 1633⟩ Used in section 4.

⟨Break the current page at node p, put it in box 255, and put the remaining nodes on the contribution list 1071⟩ Used in section 1068.

⟨Break the paragraph at the chosen breakpoints, justify the resulting lines to the correct widths, and append them to the current vertical list 924⟩ Used in section 863.

⟨Calculate page dimensions and margins 1428⟩ Used in section 653.

⟨Calculate the length, l, and the shift amount, s, of the display lines 1203⟩ Used in section 1199.

⟨Calculate the natural width, w, by which the characters of the final line extend to the right of the reference point, plus two ems; or set $w \leftarrow max\_dimen$ if the non-blank information on that line is affected by stretching or shrinking 1200⟩ Used in section 1199.

⟨Call the packaging subroutine, setting $just\_box$ to the justified box 937⟩ Used in section 928.

⟨Call try_break if cur_p is a legal breakpoint; on the second pass, also try to hyphenate the next word, if cur_p is a glue node; then advance cur_p to the next node of the paragraph that could possibly be a legal breakpoint 914⟩ Used in section 911.

⟨Carry out a ligature replacement, updating the cursor structure and possibly advancing j; **goto** *continue* if the cursor doesn't advance, otherwise **goto** *done* 965⟩ Used in section 963.

⟨Case statement to copy different types and set *words* to the number of initial words not yet copied 232⟩ Used in section 231.

⟨Cases for 'Fetch the $dead\_cycles$ or the $insert\_penalties$' 1504⟩ Used in section 453.

⟨Cases for evaluation of the current term 1602, 1606, 1607, 1609⟩ Used in section 1594.

⟨Cases for fetching a dimension value 1458, 1481, 1484, 1615⟩ Used in section 458.

⟨Cases for fetching a glue value 1618⟩ Used in section 1591.

⟨Cases for fetching a mu value 1619⟩ Used in section 1591.

⟨Cases for fetching an integer value 1454, 1475, 1478, 1614⟩ Used in section 458.

⟨Cases for noads that can follow a bin_noad 776⟩ Used in section 771.

⟨Cases for nodes that can appear in an mlist, after which we **goto** $done\_with\_node$ 773⟩ Used in section 771.

⟨Cases for $alter\_integer$ 1506⟩ Used in section 1300.

⟨Cases for $conditional$ 1577, 1578, 1580⟩ Used in section 536.

⟨Cases for do_marks 1637, 1639, 1640, 1642⟩ Used in section 1636.

⟨Cases for $eq\_destroy$ 1645⟩ Used in section 305.

⟨Cases for $input$ 1560⟩ Used in section 412.

⟨Cases for $print\_param$ 1469, 1510⟩ Used in section 263.

⟨Cases for $show\_whatever$ 1487, 1501⟩ Used in section 1347.

⟨Cases of 'Let d be the natural width' that need special treatment 1547⟩ Used in section 1201.

⟨Cases of 'Print the result of command c' 1461⟩ Used in section 507.

⟨Cases of 'Scan the argument for command c' 1460⟩ Used in section 506.

⟨Cases of $assign\_toks$ for $print\_cmd\_chr$ 1468⟩ Used in section 257.

⟨Cases of $convert$ for $print\_cmd\_chr$ 1459⟩ Used in section 504.

⟨Cases of $expandafter$ for $print\_cmd\_chr$ 1574⟩ Used in section 296.

⟨Cases of $flush\_node\_list$ that arise in mlists only 740⟩ Used in section 228.

⟨Cases of $handle\_right\_brace$ where a $right\_brace$ triggers a delayed action 1139, 1154, 1172, 1186, 1187, 1222, 1227, 1240⟩ Used in section 1122.

⟨Cases of $hlist\_out$ that arise in mixed direction text only 1530⟩ Used in section 660.

⟨Cases of if_test for $print\_cmd\_chr$ 1575⟩ Used in section 523.

⟨Cases of $input$ for $print\_cmd\_chr$ 1559⟩ Used in section 411.

⟨ Check that nodes after *native_word* permit hyphenation; if not, **goto** *done1* 945 ⟩   Used in section 943.

⟨ Check that the necessary fonts for math symbols are present; if not, flush the current math lists and set *danger* ← *true* 1249 ⟩   Used in sections 1248 and 1248.

⟨ Check that the nodes following *hb* permit hyphenation and that at least *l_hyf* + *r_hyf* letters have been found, otherwise **goto** *done1* 952 ⟩   Used in section 943.

⟨ Check the "constant" values for consistency 14, 133, 320, 557, 1303 ⟩   Used in section 1386.

⟨ Check the pool check sum 53 ⟩   Used in section 52.

⟨ Check variable-size *avail* list 194 ⟩   Used in section 192.

⟨ Clean up the memory by removing the break nodes 913 ⟩   Used in sections 863 and 911.

⟨ Clear dimensions to zero 690 ⟩   Used in sections 689 and 710.

⟨ Clear off top level from *save_stack* 312 ⟩   Used in section 311.

⟨ Close the format file 1383 ⟩   Used in section 1356.

⟨ Coerce glue to a dimension 486 ⟩   Used in sections 484 and 490.

⟨ Compiler directives 9 ⟩   Used in section 4.

⟨ Complain about an undefined family and set *cur_i* null 766 ⟩   Used in section 765.

⟨ Complain about an undefined macro 404 ⟩   Used in section 399.

⟨ Complain about missing \endcsname 407 ⟩   Used in sections 406 and 1578.

⟨ Complain about unknown unit and **goto** *done2* 494 ⟩   Used in section 493.

⟨ Complain that \the can't do this; give zero result 462 ⟩   Used in section 447.

⟨ Complain that the user should have said \mathaccent 1220 ⟩   Used in section 1219.

⟨ Compleat the incompleat noad 1239 ⟩   Used in section 1238.

⟨ Complete a potentially long \show command 1352 ⟩   Used in section 1347.

⟨ Compute $f = \lfloor 2^{28}(1 + p/q) + \frac{1}{2} \rfloor$ 117 ⟩   Used in section 116.

⟨ Compute $p = \lfloor qf/2^{28} + \frac{1}{2} \rfloor - q$ 120 ⟩   Used in section 118.

⟨ Compute $f = \lfloor xn/d + \frac{1}{2} \rfloor$ 1611 ⟩   Used in section 1610.

⟨ Compute result of *multiply* or *divide*, put it in *cur_val* 1294 ⟩   Used in section 1290.

⟨ Compute result of *register* or *advance*, put it in *cur_val* 1292 ⟩   Used in section 1290.

⟨ Compute the amount of skew 785 ⟩   Used in section 781.

⟨ Compute the badness, b, of the current page, using *awful_bad* if the box is too full 1061 ⟩   Used in section 1059.

⟨ Compute the badness, b, using *awful_bad* if the box is too full 1029 ⟩   Used in section 1028.

⟨ Compute the demerits, d, from r to *cur_p* 907 ⟩   Used in section 903.

⟨ Compute the discretionary *break_width* values 888 ⟩   Used in section 885.

⟨ Compute the hash code h 288 ⟩   Used in section 286.

⟨ Compute the magic offset 813 ⟩   Used in section 1391.

⟨ Compute the mark pointer for mark type t and class *cur_val* 1635 ⟩   Used in section 420.

⟨ Compute the minimum suitable height, w, and the corresponding number of extension steps, n; also set *width*(b) 757 ⟩   Used in section 756.

⟨ Compute the new line width 898 ⟩   Used in section 883.

⟨ Compute the primitive code h 291 ⟩   Used in section 289.

⟨ Compute the register location l and its type p; but **return** if invalid 1291 ⟩   Used in section 1290.

⟨ Compute the sum of two glue specs 1293 ⟩   Used in section 1292.

⟨ Compute the sum or difference of two glue specs 1605 ⟩   Used in section 1603.

⟨ Compute the trie op code, v, and set $l \leftarrow 0$ 1019 ⟩   Used in section 1017.

⟨ Compute the values of *break_width* 885 ⟩   Used in section 884.

⟨ Consider a node with matching width; **goto** *found* if it's a hit 648 ⟩   Used in section 647.

⟨ Consider the demerits for a line from r to *cur_p*; deactivate node r if it should no longer be active; then **goto** *continue* if a line from r to *cur_p* is infeasible, otherwise record a new feasible break 899 ⟩   Used in section 877.

⟨ Constants in the outer block 11 ⟩   Used in section 4.

⟨ Construct a box with limits above and below it, skewed by *delta* 794 ⟩   Used in section 793.

⟨ Construct a sub/superscript combination box x, with the superscript offset by *delta* 803 ⟩   Used in section 800.

⟨ Construct a subscript box x when there is no superscript 801 ⟩   Used in section 800.

⟨ Construct a superscript box x 802 ⟩   Used in section 800.

⟨ Construct a vlist box for the fraction, according to *shift_up* and *shift_down* 791 ⟩   Used in section 787.

⟨ Construct an extensible character in a new box b, using recipe *rem_byte*(q) and font f 756 ⟩   Used in section 753.

⟨ Contribute an entire group to the current parameter 433 ⟩   Used in section 426.

⟨ Contribute the recently matched tokens to the current parameter, and **goto** *continue* if a partial match is still in effect; but abort if $s = null$ 431 ⟩   Used in section 426.

⟨ Convert a final *bin_noad* to an *ord_noad* 772 ⟩   Used in sections 769 and 771.

⟨ Convert *cur_val* to a lower level 463 ⟩   Used in section 447.

⟨ Convert math glue to ordinary glue 775 ⟩   Used in section 773.

⟨ Convert *nucleus*(q) to an hlist and attach the sub/superscripts 798 ⟩   Used in section 771.

⟨ Convert string s into a new pseudo file 1565 ⟩   Used in section 1564.

⟨ Copy the tabskip glue between columns 843 ⟩   Used in section 839.

⟨ Copy the templates from node *cur_loop* into node p 842 ⟩   Used in section 841.

⟨ Copy the token list 501 ⟩   Used in section 500.

⟨ Create a character node p for *nucleus*(q), possibly followed by a kern node for the italic correction, and set *delta* to the italic correction if a subscript is present 799 ⟩   Used in section 798.

⟨ Create a character node q for the next character, but set $q \leftarrow null$ if problems arise 1178 ⟩   Used in section 1177.

⟨ Create a new array element of type t with index i 1631 ⟩   Used in section 1630.

⟨ Create a new glue specification whose width is *cur_val*; scan for its stretch and shrink components 497 ⟩   Used in section 496.

⟨ Create a page insertion node with *subtype*$(r) = qi(n)$, and include the glue correction for box n in the current page state 1063 ⟩   Used in section 1062.

⟨ Create an active breakpoint representing the beginning of the paragraph 912 ⟩   Used in section 911.

⟨ Create and append a discretionary node as an alternative to the unhyphenated word, and continue to develop both branches until they become equivalent 968 ⟩   Used in section 967.

⟨ Create equal-width boxes x and z for the numerator and denominator, and compute the default amounts *shift_up* and *shift_down* by which they are displaced from the baseline 788 ⟩   Used in section 787.

⟨ Create new active nodes for the best feasible breaks just found 884 ⟩   Used in section 883.

⟨ Create the *format_ident*, open the format file, and inform the user that dumping has begun 1382 ⟩   Used in section 1356.

⟨ Current *mem* equivalent of glue parameter number n 250 ⟩   Used in sections 176 and 178.

⟨ Deactivate node r 908 ⟩   Used in section 899.

⟨ Declare ε-T$_{\textrm{E}}$X procedures for expanding 1563, 1621, 1626, 1630 ⟩   Used in section 396.

⟨ Declare ε-T$_{\textrm{E}}$X procedures for scanning 1492, 1583, 1592, 1597 ⟩   Used in section 443.

⟨ Declare ε-T$_{\textrm{E}}$X procedures for token lists 1493, 1564 ⟩   Used in section 499.

⟨ Declare ε-T$_{\textrm{E}}$X procedures for tracing and input 314, 1471, 1472, 1567, 1568, 1585, 1587, 1588, 1632, 1634, 1648, 1649, 1650, 1651, 1652 ⟩   Used in section 298.

⟨ Declare ε-T$_{\textrm{E}}$X procedures for use by *main_control* 1466, 1489, 1505 ⟩   Used in section 863.

⟨ Declare action procedures for use by *main_control* 1097, 1101, 1103, 1104, 1105, 1108, 1114, 1115, 1118, 1123, 1124, 1129, 1133, 1138, 1140, 1145, 1147, 1149, 1150, 1153, 1155, 1157, 1159, 1164, 1167, 1171, 1173, 1177, 1181, 1183, 1185, 1189, 1190, 1192, 1196, 1205, 1209, 1213, 1214, 1217, 1219, 1226, 1228, 1230, 1235, 1245, 1248, 1254, 1265, 1324, 1329, 1333, 1342, 1347, 1356, 1403, 1439 ⟩   Used in section 1084.

⟨ Declare math construction procedures 777, 778, 779, 780, 781, 787, 793, 796, 800, 810 ⟩   Used in section 769.

⟨ Declare procedures for preprocessing hyphenation patterns 998, 1002, 1003, 1007, 1011, 1013, 1014, 1020 ⟩   Used in section 996.

⟨ Declare procedures needed for displaying the elements of mlists 733, 734, 736 ⟩   Used in section 205.

⟨ Declare procedures needed for expressions 1593, 1598 ⟩   Used in section 496.

⟨ Declare procedures needed in *do_extension* 1404, 1405, 1445, 1456 ⟩   Used in section 1403.

⟨ Declare procedures needed in *hlist_out*, *vlist_out* 1431, 1433, 1436, 1529, 1533 ⟩   Used in section 655.

⟨ Declare procedures that need to be declared forward for pdfT$_{\textrm{E}}$X 1411 ⟩   Used in section 198.

⟨Declare procedures that scan font-related stuff 612, 613⟩   Used in section 443.

⟨Declare procedures that scan restricted classes of integers 467, 468, 469, 470, 471, 1622⟩   Used in section 443.

⟨Declare subprocedures for *after_math* 1555⟩   Used in section 1248.

⟨Declare subprocedures for *init_math* 1544, 1549⟩   Used in section 1192.

⟨Declare subprocedures for *line_break* 874, 877, 925, 944, 996⟩   Used in section 863.

⟨Declare subprocedures for *prefixed_command* 1269, 1283, 1290, 1297, 1298, 1299, 1300, 1301, 1311, 1319⟩   Used in section 1265.

⟨Declare subprocedures for *scan_expr* 1604, 1608, 1610⟩   Used in section 1593.

⟨Declare subprocedures for *var_delimiter* 752, 754, 755⟩   Used in section 749.

⟨Declare subroutines for *new_character* 616, 744⟩   Used in section 617.

⟨Declare the function called *do_marks* 1636⟩   Used in section 1031.

⟨Declare the function called *fin_mlist* 1238⟩   Used in section 1228.

⟨Declare the function called *open_fmt_file* 559⟩   Used in section 1357.

⟨Declare the function called *reconstitute* 960⟩   Used in section 944.

⟨Declare the procedure called *align_peek* 833⟩   Used in section 848.

⟨Declare the procedure called *fire_up* 1066⟩   Used in section 1048.

⟨Declare the procedure called *get_preamble_token* 830⟩   Used in section 822.

⟨Declare the procedure called *handle_right_brace* 1122⟩   Used in section 1084.

⟨Declare the procedure called *init_span* 835⟩   Used in section 834.

⟨Declare the procedure called *insert_relax* 413⟩   Used in section 396.

⟨Declare the procedure called *macro_call* 423⟩   Used in section 396.

⟨Declare the procedure called *print_cmd_chr* 328, 1457⟩   Used in section 278.

⟨Declare the procedure called *print_skip_param* 251⟩   Used in section 205.

⟨Declare the procedure called *runaway* 336⟩   Used in section 141.

⟨Declare the procedure called *show_token_list* 322⟩   Used in section 141.

⟨Decry the invalid character and **goto** *restart* 376⟩   Used in section 374.

⟨Delete $c - $ "0" tokens and **goto** *continue* 92⟩   Used in section 88.

⟨Delete the page-insertion nodes 1073⟩   Used in section 1068.

⟨Destroy the t nodes following q, and make r point to the following node 931⟩   Used in section 930.

⟨Determine horizontal glue shrink setting, then **return** or **goto** *common_ending* 706⟩   Used in section 699.

⟨Determine horizontal glue stretch setting, then **return** or **goto** *common_ending* 700⟩   Used in section 699.

⟨Determine the displacement, d, of the left edge of the equation, with respect to the line size z, assuming that $l = false$ 1256⟩   Used in section 1253.

⟨Determine the shrink order 707⟩   Used in sections 706, 718, and 844.

⟨Determine the stretch order 701⟩   Used in sections 700, 715, and 844.

⟨Determine the value of $height(r)$ and the appropriate glue setting; then **return** or **goto** *common_ending* 714⟩   Used in section 710.

⟨Determine the value of $width(r)$ and the appropriate glue setting; then **return** or **goto** *common_ending* 699⟩   Used in section 689.

⟨Determine vertical glue shrink setting, then **return** or **goto** *common_ending* 718⟩   Used in section 714.

⟨Determine vertical glue stretch setting, then **return** or **goto** *common_ending* 715⟩   Used in section 714.

⟨Discard erroneous prefixes and **return** 1266⟩   Used in section 1265.

⟨Discard the prefixes \long and \outer if they are irrelevant 1267⟩   Used in section 1265.

⟨Dispense with trivial cases of void or bad boxes 1032⟩   Used in section 1031.

⟨Display adjustment p 223⟩   Used in section 209.

⟨Display box p 210⟩   Used in section 209.

⟨Display choice node p 737⟩   Used in section 732.

⟨Display discretionary p 221⟩   Used in section 209.

⟨Display fraction noad p 739⟩   Used in section 732.

⟨Display glue p 215⟩   Used in section 209.

⟨Display if this box is never to be reversed 1514⟩   Used in section 210.

⟨Display insertion p 214⟩   Used in section 209.

⟨Enter *skip_blanks* state, emit a space 379⟩   Used in section 377.

⟨Error handling procedures 82, 85, 86, 97, 98, 99, 1455⟩   Used in section 4.

⟨Evaluate the current expression 1603⟩   Used in section 1594.

⟨Examine node *p* in the hlist, taking account of its effect on the dimensions of the new box, or moving it to
     the adjustment list; then advance *p* to the next node 691⟩   Used in section 689.

⟨Examine node *p* in the vlist, taking account of its effect on the dimensions of the new box; then advance *p*
     to the next node 711⟩   Used in section 710.

⟨Expand a nonmacro 399⟩   Used in section 396.

⟨Expand macros in the token list and make *link*(*def_ref*) point to the result 1434⟩   Used in sections 1431
     and 1433.

⟨Expand the next part of the input 513⟩   Used in section 512.

⟨Expand the token after the next token 400⟩   Used in section 399.

⟨Explain that too many dead cycles have occurred in a row 1078⟩   Used in section 1066.

⟨Express astonishment that no number was here 480⟩   Used in section 478.

⟨Express consternation over the fact that no alignment is in progress 1182⟩   Used in section 1181.

⟨Express shock at the missing left brace; **goto** *found* 510⟩   Used in section 509.

⟨Feed the macro body and its parameters to the scanner 424⟩   Used in section 423.

⟨Fetch a box dimension 454⟩   Used in section 447.

⟨Fetch a character code from some table 448⟩   Used in section 447.

⟨Fetch a font dimension 459⟩   Used in section 447.

⟨Fetch a font integer 460⟩   Used in section 447.

⟨Fetch a penalties array element 1677⟩   Used in section 457.

⟨Fetch a register 461⟩   Used in section 447.

⟨Fetch a token list or font identifier, provided that *level* = *tok_val* 449⟩   Used in section 447.

⟨Fetch an internal dimension and **goto** *attach_sign*, or fetch an internal integer 484⟩   Used in section 482.

⟨Fetch an item in the current node, if appropriate 458⟩   Used in section 447.

⟨Fetch first character of a sub/superscript 805⟩   Used in sections 801, 802, and 803.

⟨Fetch something on the *page_so_far* 455⟩   Used in section 447.

⟨Fetch the *dead_cycles* or the *insert_penalties* 453⟩   Used in section 447.

⟨Fetch the *par_shape* size 457⟩   Used in section 447.

⟨Fetch the *prev_graf* 456⟩   Used in section 447.

⟨Fetch the *space_factor* or the *prev_depth* 452⟩   Used in section 447.

⟨Find an active node with fewest demerits 922⟩   Used in section 921.

⟨Find hyphen locations for the word in *hc*, or **return** 977⟩   Used in section 944.

⟨Find optimal breakpoints 911⟩   Used in section 863.

⟨Find the best active node for the desired looseness 923⟩   Used in section 921.

⟨Find the best way to split the insertion, and change *type*(*r*) to *split_up* 1064⟩   Used in section 1062.

⟨Find the glue specification, *main_p*, for text spaces in the current font 1096⟩   Used in sections 1095 and 1097.

⟨Finish an alignment in a display 1260⟩   Used in section 860.

⟨Finish displayed math 1253⟩   Used in section 1248.

⟨Finish issuing a diagnostic message for an overfull or underfull hbox 705⟩   Used in section 689.

⟨Finish issuing a diagnostic message for an overfull or underfull vbox 717⟩   Used in section 710.

⟨Finish line, emit a \par 381⟩   Used in section 377.

⟨Finish line, emit a space 378⟩   Used in section 377.

⟨Finish line, **goto** *switch* 380⟩   Used in section 377.

⟨Finish math in text 1250⟩   Used in section 1248.

⟨Finish the DVI file 680⟩   Used in section 1387.

⟨Finish the extensions 1441⟩   Used in section 1387.

⟨Finish the natural width computation 1546⟩   Used in section 1200.

⟨Finish the reversed hlist segment and **goto** *done* 1540⟩   Used in section 1539.

⟨Finish *hlist_out* for mixed direction typesetting 1525⟩   Used in section 655.

⟨Fire up the user's output routine and **return** 1079⟩   Used in section 1066.

⟨ Fix the reference count, if any, and negate *cur_val* if *negative* 464 ⟩   Used in section 447.

⟨ Flush the box from memory, showing statistics if requested 677 ⟩   Used in section 676.

⟨ Flush the prototype box 1554 ⟩   Used in section 1253.

⟨ Forbidden cases detected in *main_control* 1102, 1152, 1165, 1198 ⟩   Used in section 1099.

⟨ Generate a *down* or *right* command for *w* and **return** 646 ⟩   Used in section 643.

⟨ Generate a *y0* or *z0* command in order to reuse a previous appearance of *w* 645 ⟩   Used in section 643.

⟨ Generate all ε-TEX primitives 1399, 1452, 1467, 1473, 1476, 1479, 1482, 1485, 1494, 1496, 1499, 1502, 1507, 1511, 1558, 1570, 1573, 1581, 1589, 1612, 1616, 1620, 1672, 1675 ⟩   Used in section 1451.

⟨ Get ready to compress the trie 1006 ⟩   Used in section 1020.

⟨ Get ready to start line breaking 864, 875, 882, 896 ⟩   Used in section 863.

⟨ Get the first line of input and prepare to start 1391 ⟩   Used in section 1386.

⟨ Get the next non-blank non-call token 440 ⟩   Used in sections 439, 475, 490, 538, 561, 612, 1099, 1595, and 1596.

⟨ Get the next non-blank non-relax non-call token 438 ⟩   Used in sections 437, 1132, 1138, 1205, 1214, 1265, 1280, and 1324.

⟨ Get the next non-blank non-sign token; set *negative* appropriately 475 ⟩   Used in sections 474, 482, and 496.

⟨ Get the next token, suppressing expansion 388 ⟩   Used in section 387.

⟨ Get user's advice and **return** 87 ⟩   Used in section 86.

⟨ Give diagnostic information, if requested 1085 ⟩   Used in section 1084.

⟨ Give improper \hyphenation error 990 ⟩   Used in section 989.

⟨ Global variables 13, 20, 26, 30, 32, 39, 50, 54, 61, 77, 80, 83, 100, 108, 114, 121, 137, 138, 139, 140, 146, 181, 190, 199, 207, 239, 272, 279, 282, 283, 301, 316, 327, 331, 334, 335, 338, 339, 340, 363, 391, 397, 416, 421, 422, 444, 472, 481, 515, 524, 528, 547, 548, 555, 562, 567, 574, 584, 585, 590, 628, 631, 641, 652, 682, 685, 686, 695, 703, 726, 762, 767, 812, 818, 862, 869, 871, 873, 876, 881, 887, 895, 920, 940, 953, 959, 961, 975, 980, 997, 1001, 1004, 1025, 1034, 1036, 1043, 1086, 1128, 1320, 1335, 1353, 1359, 1385, 1396, 1400, 1429, 1449, 1462, 1470, 1515, 1561, 1584, 1625, 1627, 1646, 1653, 1669, 1670 ⟩   Used in section 4.

⟨ Go into display math mode 1199 ⟩   Used in section 1192.

⟨ Go into ordinary math mode 1193 ⟩   Used in sections 1192 and 1196.

⟨ Go through the preamble list, determining the column widths and changing the alignrecords to dummy unset boxes 849 ⟩   Used in section 848.

⟨ Grow more variable-size memory and **goto** *restart* 148 ⟩   Used in section 147.

⟨ Handle \readline and **goto** *done* 1572 ⟩   Used in section 518.

⟨ Handle \unexpanded or \detokenize and **return** 1498 ⟩   Used in section 500.

⟨ Handle a glue node for mixed direction typesetting 1509 ⟩   Used in sections 663 and 1537.

⟨ Handle a math node in *hlist_out* 1526 ⟩   Used in section 660.

⟨ Handle non-positive logarithm 125 ⟩   Used in section 123.

⟨ Handle saved items and **goto** *done* 1674 ⟩   Used in section 1164.

⟨ Handle situations involving spaces, braces, changes of state 377 ⟩   Used in section 374.

⟨ Hyphenate the *native_word_node* at *ha* 957 ⟩   Used in section 956.

⟨ If a line number class has ended, create new active nodes for the best feasible breaks in that class; then **return** if $r = last\_active$, otherwise compute the new *line_width* 883 ⟩   Used in section 877.

⟨ If all characters of the family fit relative to *h*, then **goto** *found*, otherwise **goto** *not_found* 1009 ⟩   Used in section 1007.

⟨ If an alignment entry has just ended, take appropriate action 372 ⟩   Used in section 371.

⟨ If an expanded code is present, reduce it and **goto** *start_cs* 385 ⟩   Used in sections 384 and 386.

⟨ If dumping is not allowed, abort 1358 ⟩   Used in section 1356.

⟨ If instruction *cur_i* is a kern with *cur_c*, attach the kern after *q*; or if it is a ligature with *cur_c*, combine noads *q* and *p* appropriately; then **return** if the cursor has moved past a noad, or **goto** *restart* 797 ⟩   Used in section 796.

⟨ If no hyphens were found, **return** 955 ⟩   Used in section 944.

⟨ If node *cur_p* is a legal breakpoint, call *try_break*; then update the active widths by including the glue in *glue_ptr(cur_p)* 916 ⟩   Used in section 914.

⟨Make sure that *page_max_depth* is not exceeded 1057⟩   Used in section 1051.

⟨Make sure that *pi* is in the proper range 879⟩   Used in section 877.

⟨Make the contribution list empty by setting its tail to *contrib_head* 1049⟩   Used in section 1048.

⟨Make the first 256 strings 48⟩   Used in section 47.

⟨Make the height of box *y* equal to *h* 782⟩   Used in section 781.

⟨Make the running dimensions in rule *q* extend to the boundaries of the alignment 854⟩   Used in section 853.

⟨Make the unset node *r* into a *vlist_node* of height *w*, setting the glue as if the height were *t* 859⟩   Used in section 856.

⟨Make the unset node *r* into an *hlist_node* of width *w*, setting the glue as if the width were *t* 858⟩   Used in section 856.

⟨Make variable *b* point to a box for (f, c) 753⟩   Used in section 749.

⟨Manufacture a control sequence name 406⟩   Used in section 399.

⟨Math-only cases in non-math modes, or vice versa 1100⟩   Used in section 1099.

⟨Merge sequences of words using native fonts and inter-word spaces into single nodes 656⟩   Used in section 655.

⟨Merge the widths in the span nodes of *q* with those of *p*, destroying the span nodes of *q* 851⟩   Used in section 849.

⟨Modify the end of the line to reflect the nature of the break and to include \rightskip; also set the proper value of *disc_break* 929⟩   Used in section 928.

⟨Modify the glue specification in *main_p* according to the space factor 1098⟩   Used in section 1097.

⟨Move down or output leaders 672⟩   Used in section 669.

⟨Move node *p* to the current page; if it is time for a page break, put the nodes following the break back onto the contribution list, and **return** to the user's output routine if there is one 1051⟩   Used in section 1048.

⟨Move node *p* to the new list and go to the next node; or **goto** *done* if the end of the reflected segment has been reached 1534⟩   Used in section 1533.

⟨Move pointer *s* to the end of the current list, and set *replace_count*(*r*) appropriately 972⟩   Used in section 968.

⟨Move right or output leaders 663⟩   Used in section 660.

⟨Move the characters of a ligature node to *hu* and *hc*; but **goto** *done3* if they are not all letters 951⟩   Used in section 950.

⟨Move the cursor past a pseudo-ligature, then **goto** *main_loop_lookahead* or *main_lig_loop* 1091⟩   Used in section 1088.

⟨Move the data into *trie* 1012⟩   Used in section 1020.

⟨Move the non-*char_node* *p* to the new list 1535⟩   Used in section 1534.

⟨Move to next line of file, or **goto** *restart* if there is no next line, or **return** if a \read line has finished 390⟩   Used in section 373.

⟨Negate a boolean conditional and **goto** *reswitch* 1576⟩   Used in section 399.

⟨Negate all three glue components of *cur_val* 465⟩   Used in sections 464 and 1591.

⟨Nullify *width*(*q*) and the tabskip glue following this column 850⟩   Used in section 849.

⟨Numbered cases for *debug_help* 1393⟩   Used in section 1392.

⟨Open *tfm_file* for input and **begin** 598⟩   Used in section 597.

⟨Other local variables for *try_break* 878, 1655⟩   Used in section 877.

⟨Output a box in a vlist 670⟩   Used in section 669.

⟨Output a box in an hlist 661⟩   Used in section 660.

⟨Output a leader box at *cur_h*, then advance *cur_h* by *leader_wd* + *lx* 666⟩   Used in section 664.

⟨Output a leader box at *cur_v*, then advance *cur_v* by *leader_ht* + *lx* 675⟩   Used in section 673.

⟨Output a rule in a vlist, **goto** *next_p* 671⟩   Used in section 669.

⟨Output a rule in an hlist 662⟩   Used in section 660.

⟨Output leaders in a vlist, **goto** *fin_rule* if a rule or to *next_p* if done 673⟩   Used in section 672.

⟨Output leaders in an hlist, **goto** *fin_rule* if a rule or to *next_p* if done 664⟩   Used in section 663.

⟨Output node *p* for *hlist_out* and move to the next node, maintaining the condition *cur_v* = *base_line* 658⟩   Used in section 655.

⟨Output node *p* for *vlist_out* and move to the next node, maintaining the condition *cur_h* = *left_edge* 668⟩   Used in section 667.

in section 1173.

⟨ Prune unwanted nodes at the beginning of the next line 927 ⟩   Used in section 925.

⟨ Pseudoprint the line 348 ⟩   Used in section 342.

⟨ Pseudoprint the token list 349 ⟩   Used in section 342.

⟨ Push the condition stack 530 ⟩   Used in section 533.

⟨ Push the expression stack and **goto** *restart* 1599 ⟩   Used in section 1596.

⟨ Put each of TEX's primitives into the hash table 252, 256, 264, 274, 295, 364, 410, 418, 445, 450, 503, 522, 526, 588, 828, 1037, 1106, 1112, 1125, 1142, 1161, 1168, 1195, 1210, 1223, 1232, 1242, 1262, 1273, 1276, 1284, 1304, 1308, 1316, 1326, 1331, 1340, 1345, 1398 ⟩   Used in section 1390.

⟨ Put help message on the transcript file 94 ⟩   Used in section 86.

⟨ Put the characters $hu[i + 1 ..]$ into *post_break*(r), appending to this list and to *major_tail* until synchronization has been achieved 970 ⟩   Used in section 968.

⟨ Put the characters $hu[l .. i]$ and a hyphen into *pre_break*(r) 969 ⟩   Used in section 968.

⟨ Put the fraction into a box with its delimiters, and make *new_hlist*(q) point to it 792 ⟩   Used in section 787.

⟨ Put the \leftskip glue at the left and detach this line 935 ⟩   Used in section 928.

⟨ Put the optimal current page into box 255, update *first_mark* and *bot_mark*, append insertions to their boxes, and put the remaining nodes back on the contribution list 1068 ⟩   Used in section 1066.

⟨ Put the (positive) 'at' size into s 1313 ⟩   Used in section 1312.

⟨ Put the \rightskip glue after node q 934 ⟩   Used in section 929.

⟨ Read and check the font data if file exists; *abort* if the TFM file is malformed; if there's no room for this font, say so and **goto** *done*; otherwise *incr*(*font_ptr*) and **goto** *done* 597 ⟩   Used in section 595.

⟨ Read box dimensions 606 ⟩   Used in section 597.

⟨ Read character data 604 ⟩   Used in section 597.

⟨ Read extensible character recipes 609 ⟩   Used in section 597.

⟨ Read font parameters 610 ⟩   Used in section 597.

⟨ Read ligature/kern program 608 ⟩   Used in section 597.

⟨ Read next line of file into *buffer*, or **goto** *restart* if the file has ended 392 ⟩   Used in section 390.

⟨ Read one string, but return *false* if the string memory space is getting too tight for comfort 52 ⟩   Used in section 51.

⟨ Read the first line of the new file 573 ⟩   Used in section 572.

⟨ Read the other strings from the TEX.POOL file and return *true*, or give an error message and return *false* 51 ⟩   Used in section 47.

⟨ Read the TFM header 603 ⟩   Used in section 597.

⟨ Read the TFM size fields 600 ⟩   Used in section 597.

⟨ Readjust the height and depth of *cur_box*, for \vtop 1141 ⟩   Used in section 1140.

⟨ Reconstitute nodes for the hyphenated word, inserting discretionary hyphens 967 ⟩   Used in section 956.

⟨ Record a new feasible break 903 ⟩   Used in section 899.

⟨ Recover from an unbalanced output routine 1081 ⟩   Used in section 1080.

⟨ Recover from an unbalanced write command 1435 ⟩   Used in section 1434.

⟨ Recycle node p 1053 ⟩   Used in section 1051.

⟨ Reduce to the case that $a, c \geq 0$, $b, d > 0$ 127 ⟩   Used in section 126.

⟨ Reduce to the case that $f \geq 0$ and $q > 0$ 119 ⟩   Used in section 118.

⟨ Remove the last box, unless it's part of a discretionary 1135 ⟩   Used in section 1134.

⟨ Replace nodes $ha .. hb$ by a sequence of nodes that includes the discretionary hyphens 956 ⟩   Used in section 944.

⟨ Replace the tail of the list by p 1241 ⟩   Used in section 1240.

⟨ Replace z by z' and compute α, β 607 ⟩   Used in section 606.

⟨ Report LR problems 1523 ⟩   Used in sections 1522 and 1541.

⟨ Report a runaway argument and abort 430 ⟩   Used in sections 426 and 433.

⟨ Report a tight hbox and **goto** *common_ending*, if this box is sufficiently bad 709 ⟩   Used in section 706.

⟨ Report a tight vbox and **goto** *common_ending*, if this box is sufficiently bad 720 ⟩   Used in section 718.

⟨ Report an extra right brace and **goto** *continue* 429 ⟩   Used in section 426.

⟨Report an improper use of the macro and abort 432⟩   Used in section 431.

⟨Report an overfull hbox and **goto** *common_ending*, if this box is sufficiently bad 708⟩   Used in section 706.

⟨Report an overfull vbox and **goto** *common_ending*, if this box is sufficiently bad 719⟩   Used in section 718.

⟨Report an underfull hbox and **goto** *common_ending*, if this box is sufficiently bad 702⟩   Used in section 700.

⟨Report an underfull vbox and **goto** *common_ending*, if this box is sufficiently bad 716⟩   Used in section 715.

⟨Report overflow of the input buffer, and abort 35⟩   Used in sections 31 and 1567.

⟨Report that an invalid delimiter code is being changed to null; set *cur_val* ← 0 1215⟩   Used in section 1214.

⟨Report that the font won't be loaded 596⟩   Used in section 595.

⟨Report that this dimension is out of range 495⟩   Used in section 482.

⟨Reset *cur_tok* for unexpandable primitives, goto restart 403⟩   Used in sections 447 and 474.

⟨Resume the page builder after an output routine has come to an end 1080⟩   Used in section 1154.

⟨Retrieve the prototype box 1553⟩   Used in sections 1248 and 1248.

⟨Reverse an hlist segment and **goto** *reswitch* 1532⟩   Used in section 1527.

⟨Reverse the complete hlist and set the subtype to *reversed* 1531⟩   Used in section 1524.

⟨Reverse the links of the relevant passive nodes, setting *cur_p* to the first breakpoint 926⟩   Used in section 925.

⟨Save current position to *pdf_last_x_pos*, *pdf_last_y_pos* 1427⟩   Used in sections 1426 and 1430.

⟨Scan a control sequence and set *state* ← *skip_blanks* or *mid_line* 384⟩   Used in section 374.

⟨Scan a factor f of type o or start a subexpression 1596⟩   Used in section 1594.

⟨Scan a numeric constant 478⟩   Used in section 474.

⟨Scan a parameter until its delimiter string has been found; or, if $s = null$, simply scan the delimiter string 426⟩   Used in section 425.

⟨Scan a subformula enclosed in braces and **return** 1207⟩   Used in section 1205.

⟨Scan ahead in the buffer until finding a nonletter; if an expanded code is encountered, reduce it and **goto** *start_cs*; otherwise if a multiletter control sequence is found, adjust *cur_cs* and *loc*, and **goto** *found* 386⟩   Used in section 384.

⟨Scan an alphabetic character code into *cur_val* 476⟩   Used in section 474.

⟨Scan an optional space 477⟩   Used in sections 476, 482, 490, and 1254.

⟨Scan and build the body of the token list; **goto** *found* when finished 512⟩   Used in section 508.

⟨Scan and build the parameter part of the macro definition 509⟩   Used in section 508.

⟨Scan and evaluate an expression e of type l 1594⟩   Used in section 1593.

⟨Scan decimal fraction 487⟩   Used in section 482.

⟨Scan file name in the buffer 566⟩   Used in section 565.

⟨Scan for all other units and adjust *cur_val* and f accordingly; **goto** *done* in the case of scaled points 493⟩   Used in section 488.

⟨Scan for **fil** units; **goto** *attach_fraction* if found 489⟩   Used in section 488.

⟨Scan for **mu** units and **goto** *attach_fraction* 491⟩   Used in section 488.

⟨Scan for units that are internal dimensions; **goto** *attach_sign* with *cur_val* set if found 490⟩   Used in section 488.

⟨Scan preamble text until *cur_cmd* is *tab_mark* or *car_ret*, looking for changes in the tabskip glue; append an alignrecord to the preamble list 827⟩   Used in section 825.

⟨Scan the argument for command c 506⟩   Used in section 505.

⟨Scan the font size specification 1312⟩   Used in section 1311.

⟨Scan the next operator and set o 1595⟩   Used in section 1594.

⟨Scan the parameters and make *link*(*r*) point to the macro body; but **return** if an illegal \par is detected 425⟩   Used in section 423.

⟨Scan the preamble and record it in the *preamble* list 825⟩   Used in section 822.

⟨Scan the template ⟨u_j⟩, putting the resulting token list in *hold_head* 831⟩   Used in section 827.

⟨Scan the template ⟨v_j⟩, putting the resulting token list in *hold_head* 832⟩   Used in section 827.

⟨Scan units and set *cur_val* to $x \cdot (cur\_val + f/2^{16})$, where there are x sp per unit; **goto** *attach_sign* if the units are internal 488⟩   Used in section 482.

⟨Search *eqtb* for equivalents equal to p 281⟩   Used in section 197.

⟨Search *hyph_list* for pointers to p 987⟩   Used in section 197.

⟨Search *save_stack* for equivalents that point to p 315⟩ Used in section 197.

⟨Select the appropriate case and **return** or **goto** *common_ending* 544⟩ Used in section 536.

⟨Set initial values of key variables 23, 24, 62, 78, 81, 84, 101, 122, 191, 241, 280, 284, 302, 317, 398, 417, 473, 516, 525, 556, 586, 591, 629, 632, 642, 687, 696, 704, 727, 819, 941, 982, 1044, 1087, 1321, 1336, 1354, 1397, 1412, 1516, 1562, 1628, 1647, 1671⟩ Used in section 8.

⟨Set line length parameters in preparation for hanging indentation 897⟩ Used in section 896.

⟨Set the glue in all the unset boxes of the current list 853⟩ Used in section 848.

⟨Set the glue in node r and change it from an unset node 856⟩ Used in section 855.

⟨Set the unset box q and the unset boxes in it 855⟩ Used in section 853.

⟨Set the value of b to the badness for shrinking the line, and compute the corresponding *fit_class* 901⟩ Used in section 899.

⟨Set the value of b to the badness for stretching the line, and compute the corresponding *fit_class* 900⟩ Used in section 899.

⟨Set the value of b to the badness of the last line for shrinking, compute the corresponding *fit_class*, and **goto** *found* 1659⟩ Used in section 1657.

⟨Set the value of b to the badness of the last line for stretching, compute the corresponding *fit_class*, and **goto** *found* 1658⟩ Used in section 1657.

⟨Set the value of *output_penalty* 1067⟩ Used in section 1066.

⟨Set the value of x to the text direction before the display 1542⟩ Used in sections 1543 and 1545.

⟨Set up data structures with the cursor following position j 962⟩ Used in section 960.

⟨Set up the hlist for the display line 1556⟩ Used in section 1555.

⟨Set up the values of *cur_size* and *cur_mu*, based on *cur_style* 746⟩ Used in sections 763, 769, 770, 773, 798, 805, 805, 808, 810, and 811.

⟨Set variable c to the current escape character 269⟩ Used in section 67.

⟨Set variable w to indicate if this case should be reported 1586⟩ Used in sections 1585 and 1587.

⟨Ship box p out 678⟩ Used in section 676.

⟨Show equivalent n, in region 1 or 2 249⟩ Used in section 278.

⟨Show equivalent n, in region 3 255⟩ Used in section 278.

⟨Show equivalent n, in region 4 259⟩ Used in section 278.

⟨Show equivalent n, in region 5 268⟩ Used in section 278.

⟨Show equivalent n, in region 6 277⟩ Used in section 278.

⟨Show the auxiliary field, a 245⟩ Used in section 244.

⟨Show the box context 1491⟩ Used in section 1489.

⟨Show the box packaging info 1490⟩ Used in section 1489.

⟨Show the current contents of a box 1350⟩ Used in section 1347.

⟨Show the current meaning of a token, then **goto** *common_ending* 1348⟩ Used in section 1347.

⟨Show the current value of some parameter or register, then **goto** *common_ending* 1351⟩ Used in section 1347.

⟨Show the font identifier in *eqtb*[n] 260⟩ Used in section 259.

⟨Show the halfword code in *eqtb*[n] 261⟩ Used in section 259.

⟨Show the status of the current page 1040⟩ Used in section 244.

⟨Show the text of the macro being expanded 435⟩ Used in section 423.

⟨Simplify a trivial box 764⟩ Used in section 763.

⟨Skip to `\else` or `\fi`, then **goto** *common_ending* 535⟩ Used in section 533.

⟨Skip to node *ha*, or **goto** *done1* if no hyphenation should be attempted 949⟩ Used in section 943.

⟨Skip to node *hb*, putting letters into *hu* and *hc* 950⟩ Used in section 943.

⟨Sort p into the list starting at *rover* and advance p to *rlink*(p) 154⟩ Used in section 153.

⟨Sort the hyphenation op tables into proper order 999⟩ Used in section 1006.

⟨Split off part of a vertical box, make *cur_box* point to it 1136⟩ Used in section 1133.

⟨Split the *native_word_node* at l and link the second part after *ha* 947⟩ Used in sections 946 and 946.

⟨Squeeze the equation as much as possible; if there is an equation number that should go on a separate line by itself, set $e \leftarrow 0$ 1255⟩ Used in section 1253.

⟨Start a new current page 1045⟩ Used in sections 241 and 1071.

⟨Store additional data for this feasible break 1661⟩ Used in section 903.

⟨Store additional data in the new active node 1662⟩ Used in section 893.

⟨Store *cur_box* in a box register 1131⟩ Used in section 1129.

⟨Store maximum values in the *hyf* table 978⟩ Used in section 977.

⟨Store *save_stack*[*save_ptr*] in *eqtb*[*p*], unless *eqtb*[*p*] holds a global value 313⟩ Used in section 312.

⟨Store all current *lc_code* values 1667⟩ Used in section 1666.

⟨Store hyphenation codes for current language 1666⟩ Used in section 1014.

⟨Store the current token, but **goto** *continue* if it is a blank space that would become an undelimited parameter 427⟩ Used in section 426.

⟨Subtract glue from *break_width* 886⟩ Used in section 885.

⟨Subtract the width of node *v* from *break_width* 889⟩ Used in section 888.

⟨Suppress expansion of the next token 401⟩ Used in section 399.

⟨Swap the subscript and superscript into box *x* 786⟩ Used in section 781.

⟨Switch to a larger accent if available and appropriate 784⟩ Used in section 781.

⟨Switch to a larger native-font accent if available and appropriate 783⟩ Used in section 781.

⟨Tell the user what has run away and try to recover 368⟩ Used in section 366.

⟨Terminate the current conditional and skip to `\fi` 545⟩ Used in section 399.

⟨Test box register status 540⟩ Used in section 536.

⟨Test if an integer is odd 539⟩ Used in section 536.

⟨Test if two characters match 541⟩ Used in section 536.

⟨Test if two macro texts match 543⟩ Used in section 542.

⟨Test if two tokens match 542⟩ Used in section 536.

⟨Test relation between integers or dimensions 538⟩ Used in section 536.

⟨The em width for *cur_font* 593⟩ Used in section 490.

⟨The x-height for *cur_font* 594⟩ Used in section 490.

⟨Tidy up the parameter just scanned, and tuck it away 434⟩ Used in section 426.

⟨Transfer node *p* to the adjustment list 697⟩ Used in section 691.

⟨Transplant the post-break list 932⟩ Used in section 930.

⟨Transplant the pre-break list 933⟩ Used in section 930.

⟨Treat *cur_chr* as an active character 1206⟩ Used in sections 1205 and 1209.

⟨Try the final line break at the end of the paragraph, and **goto** *done* if the desired breakpoints have been found 921⟩ Used in section 911.

⟨Try to allocate within node *p* and its physical successors, and **goto** *found* if allocation was possible 149⟩ Used in section 147.

⟨Try to break after a discretionary fragment, then **goto** *done5* 917⟩ Used in section 914.

⟨Try to get a different log file name 570⟩ Used in section 569.

⟨Try to hyphenate the following word 943⟩ Used in section 914.

⟨Try to recover from mismatched `\right` 1246⟩ Used in section 1245.

⟨Types in the outer block 18, 25, 38, 105, 113, 135, 174, 238, 299, 330, 583, 630, 974, 979, 1488⟩ Used in section 4.

⟨Undump a couple more things and the closing check word 1381⟩ Used in section 1357.

⟨Undump constants for consistency check 1362⟩ Used in section 1357.

⟨Undump regions 1 to 6 of *eqtb* 1371⟩ Used in section 1368.

⟨Undump the ε-TEX state 1465⟩ Used in section 1362.

⟨Undump the array info for internal font number *k* 1377⟩ Used in section 1375.

⟨Undump the dynamic memory 1366⟩ Used in section 1357.

⟨Undump the font information 1375⟩ Used in section 1357.

⟨Undump the hash table 1373⟩ Used in section 1368.

⟨Undump the hyphenation tables 1379⟩ Used in section 1357.

⟨Undump the string pool 1364⟩ Used in section 1357.

⟨Undump the table of equivalents 1368⟩ Used in section 1357.

⟨Update the active widths, since the first active node has been deleted 909⟩ Used in section 908.

⟨ Update the current height and depth measurements with respect to a glue or kern node p 1030 ⟩   Used in
      section 1026.

⟨ Update the current marks for *fire_up* 1641 ⟩   Used in section 1068.

⟨ Update the current marks for *vsplit* 1638 ⟩   Used in section 1033.

⟨ Update the current page measurements with respect to the glue or kern specified by node p 1058 ⟩   Used in
      section 1051.

⟨ Update the value of *printed_node* for symbolic displays 906 ⟩   Used in section 877.

⟨ Update the values of *first_mark* and *bot_mark* 1070 ⟩   Used in section 1068.

⟨ Update the values of *last_glue*, *last_penalty*, and *last_kern* 1050 ⟩   Used in section 1048.

⟨ Update the values of *max_h* and *max_v*; but if the page is too large, **goto** *done* 679 ⟩   Used in section 678.

⟨ Update width entry for spanned columns 846 ⟩   Used in section 844.

⟨ Use code c to distinguish between generalized fractions 1236 ⟩   Used in section 1235.

⟨ Use node p to update the current height and depth measurements; if this node is not a legal breakpoint,
      goto *not_found* or *update_heights*, otherwise set *pi* to the associated penalty at the break 1027 ⟩   Used
      in section 1026.

⟨ Use size fields to allocate font information 601 ⟩   Used in section 597.

⟨ Wipe out the whatsit node p and **goto** *done* 1418 ⟩   Used in section 228.

⟨ Wrap up the box specified by node r, splitting node p if called for; set *wait* ← *true* if node p holds a
      remainder after splitting 1075 ⟩   Used in section 1074.
